32. **Glioma at Base of Brain.**—The special feature of Halipré's case was that the functioning of the third pair was not interfered with by the large, soft, three-lobed glioma in the base of the brain, involving the internal capsule. The optic nerves embedded in the tumor were completely destroyed, but the right third nerve, although traversing the tumor, was apparently intact and no symptoms had been observed from it. The patient was a girl of 11; the first symptoms of the tumor had been observed four years before death. They consisted at first mainly in convulsions and hemiparesis, all improving under bromids.

40 *Spontaneous Delivery with Rachitic Contracted Pelvis. M. Marioton.

40. **Spontaneous Delivery with Contracted Pelvis.**—Marioton reviews the experiences in this line at the Clinique Tarnier at Paris, in charge of Bar, with 180 cases during the last two years, striving to determine the probabilities for delivery without assistance in the various grades of rachitic contracted pelvis. This anomaly seems to have grown less and less frequent during the last half century, not only at this clinic, but according to the reports from six other maternities of Paris. The maternal mortality was as low for the women with contracted pelvis—when delivery was spontaneously terminated—as for women with normal pelves. The mortality was only 0.6 per cent., while the general obstetric mortality is now estimated at 0.5 per cent. The statistics from various clinics and the management of the cases are tabulated for comparison. The data show that with a minimum conjugate diameter (*diamètre promonto-pubien minimum*, estimated by subtracting 1.5 cm. from the diagonal conjugate), of over 9 cm., delivery is spontaneously completed in 80 per cent. of all cases; below 8 cm. this rarely occurs—not in over 25 per cent. Between these limits of 8 and 9 cm. (3⅜ and 3⅝ inches) is the debatable ground. The dividing line seems to lie between 8.5 and 8.6 up to 8.9 cm. Below 8.5, assistance is generally necessary in more than 50 per cent. of the cases. The statistics cited show that spontaneous delivery occurs 10 to 11 per cent. more frequently in women who have already borne children. With pelves over 8.6 cm., the fetal mortality scarcely surpassed that with normal pelves, being about 9 per cent., while with pelves of less than 8 cm. fully 30 per cent. of the fetuses succumbed. The influence of preceding births did not seem to affect the fetal mortality, but infants weighing not much over 5 pounds died in a proportion ranging from 22.85 to 80 per cent., irrespective of the degree of contraction of the pelvis. With infants weighing from 5 to 6 pounds and a trifle over, the mortality was from 6 to 8 per cent., increasing to 20 per cent. with pelves between 8.1 and 8.5 cm. Under 5 and 6 pounds, with a conjugate diameter of 8 cm., the mortality is a little less than for the heavier children, but it amounted to 33 and 50 per cent. The data presented show that the fact of the contracted pelvis *in itself* does not render the prognosis for the mother any more serious.

42 *Treatment of Surgical Tuberculosis of Bones and Joints. (Des progrès réalisés dans le traitement chirurgical des tuberculoses ostéoarticulaires.) P. Vignard and R. Armand.

42. **Treatment of Surgical Tuberculosis of Bones and Joints.**—Vignard and Armand conclude their long article, which is accompanied by thirty-one skiagraphs of some of the cases reported, with the statement that the natural tendency toward a cure of tuberculosis, especially in the joints in the young, imposes the necessity for prolonged immobilization as the best treatment in such cases. Local injections may be advisable as an adjuvant, especially in residual abscesses after healing over of the bone lesions. They have no action on the latter, as it is impossible for them to reach all parts of the lesion effectually, and the fluid injected has no effect on bone tissue, but in a synovial or abscess pocket they may do good service. Whenever a focus of tuberculous osteitis is accessible, it should be cleared out, and operative treatment is also indicated for a joint lesion if no turn for the better is apparent after five or ten months of immobilization. The operation should be concluded by plugging the cavity left in bone or joint with Mosetig filling. Everything must be done to avoid the necessity for drainage, at least for any length of time. Treatment on these principles is applicable only in cases in which there is no fistula and the kidneys are sound.

44 *Central Nervous System of Children with Inherited Taints. II. (Le système nerveux central d'enfants issus de parents en état morbide.) G. Catola.

44. **Nervous System with Inherited Taints.**—The conception of an inherited predisposition to disease is sustained by the histologic findings in the central nervous system in eight children examined by Catola. The mothers had had tuberculosis, nephritis, pernicious anemia or syphilis, and the nerve tissue in the children showed imperfect or otherwise abnormal structure. The toxins seem to be able to induce hypoplasia or hyperplasia, affording an anatomic basis for the predisposition to disease in such families.

45 *Diffuse Calcification of Connective and Subcutaneous Tissue. (La calcinose généralisée et ses formes anatomiques interstitielle et sous-cutanée.) J. Lhermitte.

45. **Diffuse Calcification of Connective and Subcutaneous Tissue.**—Lhermitte calls attention to an anatomic-clinical syndrome characterized by infiltration with lime of the subcutaneous and connective tissue. This generalized calcinosis, as he calls it, is liable to affect both sexes, but is most frequent between the ages of 8 and 20. None of the specific infections seems to have anything to do with it, unless possibly syphilis. Krause and Trappe noticed marked improvement in their case under mercurial treatment, although there were no signs of syphilis and the Wassermann reaction was negative. Mercurial treatment was even more effectual in Stradiotti's case in which there was a history of untreated syphilis in youth; at the age of 44 a profusion of subcutaneous nodules containing lime subsided under mercurial treatment. The data reported seem to indicate further a close connection between this diffuse calcinosis and scleroderma. In a number of the cases on record there was irregular, pronounced enlargement of the thyroid. In many cases local trauma seemed to be responsible for the first development of the subcutaneous form of the affection. The interstitial or muscle-

tendon type is less frequent, but much more serious The two forms have been observed together in some cases, and both are liable to be accompanied by vasomotor disturbances, sclerema, changes in the skin and pigmentation

48 **Test for Free Acid in Stomach Content.**—One hour after a test breakfast the patient drinks a swallow of an aqueous solution of sodium bicarbonate while the physician is auscultating him The arrival of the fluid in the stomach can be readily heard and also in a few minutes, the sounds of effervescence in case there is hydrochloric acid present in the stomach content Fuld has not been able to find any effervescence auscultation test previously described in the literature The effervescence can be detected also by Roentgen ray examination, and if the patient is told to stand up there is generally an eructation The only source of error liable is when there is gas already in the stomach from fermentation This possibility should be excluded by auscultation before giving the soda The method is so simple and easy that the test can be repeatedly applied without inconvenience to the patient The amount of acid present can be approximately estimated by having the patient take another sip of the soda solution If there is no further effervescence, the first sip must have neutralized all the free acid With hyperacidity several sips are necessary to accomplish this He estimates at 75 per cent the proportion of cases of gastric cancer in which the secretion of hydrochloric acid has been arrested Consequently the above simple means for determining the presence or absence of free acid in the stomach should be included, he declares in every routine examination of a patient passing middle life, just as the urine is examined for albumin and sugar

55 **Screenless Fluoroscopy**—Bauer applies to the skin, instead of to the screen, the coating of fluorescent paint This is done by drawing over the part a tricot cover coated with the platino cyanid of barium The result is surprising and fascinating, as the parts thus become luminous, free from the drawbacks of projection of the object on a plane surface The chemical is applied to the inside of the tricot cuff or bandage, which is then drawn over or wound around the part to be examined It then becomes actually transparent, so far as the soft parts are concerned, while the bones stand out in normal relief

58 **Peptid Splitting Ferment in Stomach Content**—Kuttner and Pulvermacher state that the findings with the glycyl tryptophan test (described in THE JOURNAL, Jan 1, 1910, page 86) and their modification of it failed to confirm the assumption that the findings can be utilized in the diagnosis of stomach affections, especially of gastric cancer However, the findings seem to throw light on the functioning of the pancreas and the test may prove useful for this purpose.

66 Summarized in these columns, Sept 24, 1910, page 1156

68 **Chronic Intestinal Disease and Bone Disease**—In the first of the four cases reported by Koll, intestinal disturbances had persisted for years, with fetid diarrhea at times In each case the bones showed marked and progressive disturbances in development softening or hyperplasia and abnormal development of the epiphyses In two of the cases there does not seem to be any doubt that the bowel trouble was mainly responsible for the abnormal conditions in the bones, the cure of the latter as the bowel trouble was cured confirms this assumption There is every probability that the same factor was responsible in the other two cases The patients were women between 18 and 29 years old and one man of 73 The diarrhea began in early childhood in three of the cases and at the age of 24 in the other, and it had recurred at intervals during the years since, the features of the diarrhea indicating some affection of the small and upper large intestine There was a suspicion of tuberculous infection as the cause of the intestinal trouble in each case, confirmed by necropsy in one. but the complete recovery in two other cases scarcely sustains this assumption The bone anomalies suggested osteomalacia in one case, rachitis in two and acromegaly in the other The facts observed suggest that bone affections of this kind should be regarded not so much from the standpoint of strict differential diagnosis, but should be considered as the local manifestations of some constitutional chemical process of intoxication

69 **Parasitic Hemoptysis**—The patient in Abend's case was a miller 44 years old, who had been living in the United States for twenty years, working on railroad construction and in mills, and coughing up blood occasionally during the last ten years Each morning he spit up a little blood, but never at other times and he had no dyspnea nor pain, but sometimes a sense of oppression and formication in the region of the left lower ribs, with occasional vertigo Otherwise he felt well, and after thus expectorating blood for about twenty four years, suddenly it ceased and the man has been well since Abend found in the sputum the ova of some parasite, which he believes is the *Distomum pulmonale*, and the Roentgen rays show several small pinhead oval shadows in the center of the lung, similar to the miliary nodules which Miura found in some cases of supposed distomiasis No fatal hemorrhage from this cause is on record

74 **Carbohydrate Metabolism**—Wacker and Poly report research on the normal sugar content of the human blood. sugar in various parts of the vascular regions in the dog and rabbit, hyperglycemia and the permeability of the kidneys for sugar, chemical regulation of body temperature, fever and action of antipyretics and the sugar content of the blood in pathologic conditions in 126 patients

75 **Research on Fever**—The findings in eighty cases of various acute infectious diseases are compared and certain

laws are seen to prevail indicating a close connection between the course of the fever and the bacterial content of the blood. These assumptions were confirmed by experiments on animals. It proved possible to prevent fatal collapse in animals after injection of bacterial toxins by keeping them extra warm just before and following the injections, thus preventing the reduction of temperature otherwise constant after the injections. Anything tending to induce hypersusceptibility may upset the temperature balance. Disturbances in the temperature regulation and formation of antibodies are signs of the altered reaction capacity of the organism, but the central nervous system is the chief point of attack for the toxins and endotoxins. When the nervous centers are intensely affected, phenomena of collapse follow, drop in temperature and blood-pressure, and inability to produce antibodies; when the nerve-centers are only moderately affected, the temperature rises and antibodies are produced unhindered.

76. **Diagnosis of Gastric Cancer from Hemolysis by Stomach Content.**—Gräfe and Röhmer say that the presence of oleic acid in the stomach content, which is responsible for the hemolysis observed, is not specific for cancer, but it indicates something wrong, and in conjunction with other symptoms is proving a valuable aid in differentiation of malignant disease. A previous communication on the subject was summarized in The Journal, Oct. 29, 1910, page 1602.

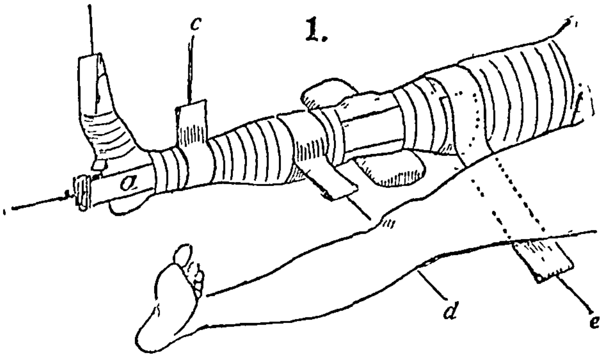
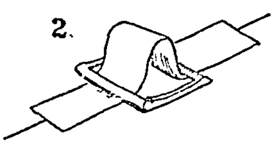
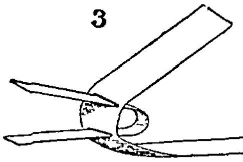
79. **Extension in Treatment of Fractures.**—Bardenheuer presents here the conclusions of his years of pioneer work in this line, describing the technic for continuous elastic traction in various directions, which he regards as the best means to restore normal functioning to fractured limbs. The contraction of the muscles is often the chief hindrance to reduction of the fracture, and consequently, he says, extension should be applied as early as possible after the fracture, and it should be strong enough to overcome the elastic inflammatory retraction of the muscles. As the muscles act not only lengthwise of the limb, but also concentrically, traction must be exerted from the sides as well as from the end of the limb, and be adapted to counteract any tendency to rotation. By exact apposition of the stumps the tendency to production of callus is reduced to the minimum, which is extremely important for the future functioning of the limb; the aim should be to reduce the healing of the stumps to a linear scar, just as in the healing of a skin wound. Healing by primary intention of a skin wound is always the shorter process, and it is the same with healing of the fracture. Forcible reduction is rendered unnecessary with the extension technic, as this gradually brings the stumps into their normal position, unless the displacement is extreme. When it has to be done he gives ether. A good functional result can be anticipated only when the elasticity of the muscles and of all the tissues is maintained unimpaired. They lose their elasticity more and more the longer they are inactive, and most so when there is concomitant inflammation. By the elastic traction of his extension technic the retracted muscles are stretched while the stumps having been restored to normal position, there is no further irritation from them on the soft parts and resulting inflammation is prevented, checked or its consequences attenuated. He commences active motion with a fractured wrist as early as the fourth day, the fifth with fractured ankle, the third week with fractured knee, exercising the joint for half an hour twice a day. The excursions should be merely what can be done without pain. The weights are removed when the limb is being exercised. The patient lies on a hair mattress, or a board can be placed under the limb. The adhesive plaster must be non-irritating, 6 cm. wide for the lengthwise strips and half this width wound around the limb. The front of the tibia and the malleoli are protected by folded gauze;



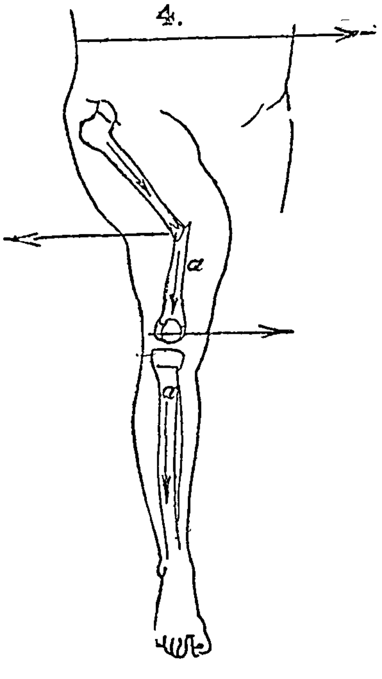
1.



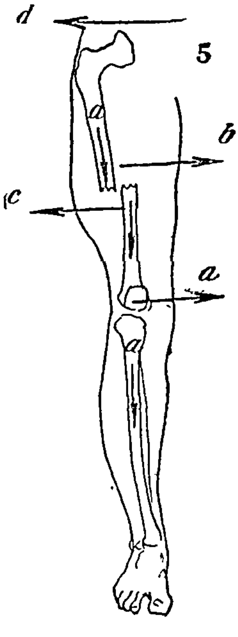
2.



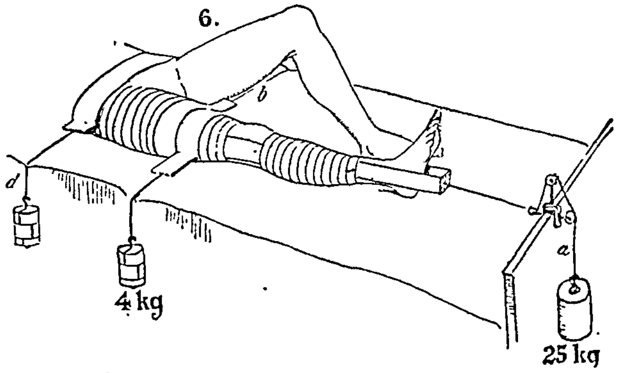
3



4.



5



6.

cotton becomes lumpy. The extension is applied to the region of the stumps with counterextension for the farther end of the bone, as in Figure 4. He advocates extension on these principles for all simple fractures of the extremities; for dislocations after reduction, as the Roentgen rays show that dislocations are almost always accompanied by more or less splitting off of bone or lacerations, and also for all compound fractures of the extremities if the skin has been merely pierced by the bone, or if the soft parts are not seriously injured and there is reason to assume absence of infection. He disapproves of plaster casts in all cases of fracture, except when needed for transportation of the patient, especially in war; for the delirious, to prevent self-injury; for exceptional circumstances in which a walking apparatus is required, for after treatment of fractured bones that have been surgically united—in both these last classes the plaster cast must be made removable to permit exercise of the limb—and, lastly, for compound fractures when the size, location, extent and nature of the injury may require immobilization in a solid cast

Figure 1 shows the extension for fracture of the leg not far below the knee; Figure 2 shows the device by which downward traction can be applied from each side; Figure 3 the plaster crossed to pull split off parts of bone into apposition. Figure 4 shows the direction of traction, and Figure 6 shows the same in application, while Figure 5 calls for traction in different directions He uses a spring extension apparatus for fracture of the arm The traction applied to the waist is to keep the patient from moving around.

80. **Convulsions After Orthopedic Operations.**—Codivilla has encountered nine cases of this kind, Schanz ten, and Hoffa. Drehmann and others have reported some fatal cases The convulsions are a severe complication of the operation, and Codivilla thinks that there can be no doubt that they are the result of traction on the nerve terminals by the extension applied to complete the operative correction of the deformity in question. The excessive traction on the soft parts and nerves of the hips affects by reflex action the central nervous system, entailing a condition which leads to the outbreak of actual epileptic convulsions. Neri has confirmed by experiments on animals the correctness of this view of the traction on the nerves in the region as the cause for the convulsions, especially the continuous traction on the sciatic nerve. Children and adults with a predisposition to nervous disturbances are particularly liable to be affected. The main point in treatment of the attack or in prevention is to relieve the traction on the soft parts, either by loosening the extension or by placing the hip in a position to prevent the excessive traction on the soft parts. He advises a preliminary course of bromid for epileptics and all persons inclined to be unusually nervous, and, when the soft parts have to be stretched, to do this very cautiously and gradually. In his cases the convulsions did not develop until several days after the operation; they were usually preceded by prodromal manifestations· more or less headache, the patient is particularly restless at night and unable to sleep, with occasional painful spasms in the limb Children do not cry but moan almost uninterruptedly, while older patients keep sighing and complain of distress, and there may be a tendency to delirium, especially at night The pulse is slow and tense, the pupils mydriatic, the light reaction sluggish and incomplete, and the pupils may be unequal The patients may complain of abdominal pain and difficulty in urinating. This prodromal stage may last for hours or days and may subside without development of actual convulsions. The convulsions generally begin mild and brief, but grow gradually worse until the spasms are practically continuous During the pauses the patient may regain consciousness, but generally there is more or less apathy or stupor. The convulsions resemble an epileptic seizure in every particular, he states Schanz ascribes them to fat embolism, but there are numerous arguments against this view.

81. **Tests of Kidney Functioning.**—In this postgraduate lecture Casper lauds the great advances made in functional tests of the kidneys which have revolutionized the prognosis of *nephrectomy. He adds that the tests are also proving of great* value in determining the indications for prostatectomy, as the chances for a successful outcome are better the sounder the kidneys.

87. **Special Diets at Health Resorts and in Institutions.**—Schlesinger commends the introduction at Homburg and some other watering places of special menus for certain classes of visitors in search of health, saying that these special diets represent a great advance. But he thinks that the menus provided might be improved on, and he suggests menus for four diets graduated to the digestive capacity of the individual rather than to the special organ which may be diseased. The menus outlined are comprehensive enough for ample individualization for indications and tastes. Diet 1 is a fluid diet for the very sick. Diet 2 is designed to spare the stomach all extra work; all the articles are passed through a sieve or very finely chopped, and extensive use is made of beaten whites of eggs which serve the useful purpose of keeping the particles of the food apart and rendering them still more porous as the dish is cooked. Meat is allowed only at noon. Diet 3 is mainly a milk and vegetable diet, free from meat and extractives, and Diet 4 is for diabetics, excluding sugar and flour. All the menus are arranged for three meals a day, plus two light lunches.

90. **Blood-Pressure in Children.**—Kaupe's findings parallel those of Seiler and Kriss already mentioned in THE JOURNAL, Sept. 3, 1910, page 893.

91. **Salt Fever.**—It seems evident from the research reported that "salt fever" is the result of heat congestion in the interior as the water normally eliminated in perspiration is drawn away from the skin by the influence of the salt. Drinking water restores the proper balance The fever with the retained water is only an indirect result—the salt in itself not raising the temperature.

96. **Transmission of Disease by Insects, Etc.**—Muller gives a nearly two-column list of arthropods, insects, spiders, etc., important from a medical point of view as transmitters of disease, and discusses what has been learned on the subject *to date.*

101. Spinal Anesthesia.—Zweifel states that the spinal technic has been applied in 1,500 cases at Leipsic without a fatality. It is generally combined with the preliminary scopolamin-morphin technic, and this is all that the patients remember of the operation, asking as they rouse, hours after the operation, when it is going to begin. The only by-effects of consequence were headache and pain in the back of the neck in about 5 or 6 per cent. of the patients. The headache persisted on an average for two days; it was aggravated in some cases by the slightest movement of the head. One patient still had headache when dismissed from the hospital six weeks after the operation. Headache developed in 8 per cent. of the eighty-eight vaginal operations, and only in 2 per cent. of the 231 abdominal operations. In a case of herniotomy and one of the Alexander-Adams operation, the cerebrospinal fluid spurted in a strong jet, and both these patients suffered from constant vomiting and intense headache for one or two days, the pain persisting in one case for two weeks. The disturbances in these cases were evidently the result of the changes in the pressure in the fluid, and the technic should not permit such fluctuations in the pressure.

111 Transplantation of the Biceps Femoris. (Verpflanzung des Musculus biceps femoris zur Hebung pathologischer Aussenrotation des Oberschenkels bei spinaler Kinderlähmung.) A. Hildebrandt.

109. Exercises in Treatment of Asthenic Conditions in the Abdomen.—Oldevig emphasizes the necessity for toning up the muscles as the best means for restoring normal conditions in case of ptosis of the viscera, constipation or other abdominal disturbances in which weakness of the abdominal muscles can be a factor. Exercise is the only way to strengthen the muscles, and if the muscle can be exercised singly, the greater the effect. By exercising the muscles which are under control of the will, we are able to influence the organs which are beyond this control. The special exercise which he has found most effectual in cases of ptosis, tendency to hernia and constipation, is with the patient reclining, his arms at his side and one foot laid over the other. He then lifts his pelvis as high as possible, and while he is doing this an attendant opposes resistance to this raising of the pelvis; seated on the long, low bench beside the patient he places his hands on the crests of the ilium and presses downward as the patient lifts the pelvis. When the pelvis is raised as high as the patient can bring it against the resistance of the attendant, then the attendant presses it back down on the table, the patient striving to resist this downward movement. The patient breathes deeply before he commences the exercise, and it is done during slow expiration, although it may take a little practice to do this at first. After the exercise has been done three or four times the patient rests. The exercise has a tendency to increase the heart action and the supply of the blood to the head. When the exercise is correctly done the isolated group of muscles being exercised feel as if a firm, funnel-shaped bandage were wound around the entire pelvis from the perineum to the lower part of the thorax.

110. Extra Solubility of Phosphorus in Castor Oil.—The research reported confirms the dangers of giving castor oil in case of acute phosphorus poisoning, as the phosphorus is thus rendered more soluble and larger amounts are absorbed. The same applies also probably to other drugs soluble in oil, nitrobenzol, santonin, cantharidin, etc.

115 *Principles in the Treatment of Hernia. F. Karewski.

112. Digitalis.—This is a lecture delivered by von Leyden eleven years ago, but not previously published. He urges to refrain from giving digitalis unless there is urgent need for it, and not to give it too early. It seems to be established that digitalis acts only on the left ventricle; when the right ventricle is weak digitalis acts injuriously rather than usefully, possibly increasing the dyspnea. Consequently he regards this drug as contra-indicated with mitral stenosis, with emphysema and kyphoscoliosis. If it works under these conditions it is only on account of the secondary weakness of the left ventricle. He assumes that digitalis acts only on the musculature of the heart, and consequently will have little action if a large part of the muscle is degenerated. With chronic myocarditis it frequently fails completely. Even with valvular defects, its lack of action may be explained by the isolated myocarditic foci accompanying the endocarditic process. He regards the action of digitalis as uncertain and dubious when there is fever, preferring to give 5 or 8 drops twice a day of tincture of strophanthus.

113. Prognosis of Exophthalmic Goiter.—Syllaba makes an important contribution to this subject by his study of fifty-one cases in which the history of the patients has been followed for several years, the series commencing with 1895. Treatment was exclusively medical with two exceptions, and the ultimate outcome is 19.6 per cent. improved and 33.3 cured, that is, favorable in 52.9 per cent. He reviews the experiences of others with non-operative treatment, all confirming his experience that over half of the patients with exophthalmic goiter can be permanently improved and that one-third are completely cured, or at most left with a little exophthalmos. In his seventeen cases of complete cures there were four or five in which the exophthalmic goiter was comparatively mild, but in the others the syndrome was very severe. In the two cases in which an adjuvant operation was performed there was recurrence after two years in one case and the other patient died five months afterward from asystolia; she had been left with postoperative tetany and recurrent paralysis, in addition to her previous disturbances. In the various cases treatment had been manifold and various; any medical measure may cure and all may fail. One patient is improved by one method, another may be uninfluenced by the whole arsenal. In three cases the symptoms flared up under iodin treatment, in one given internally and in the others after prolonged local applications. This experience and that of others confirm the fact that iodin seems to be a poison for patients with exophthalmic goiter. He urges the necessity for careful study of every case of exophthalmic goiter under medical treatment and perpetually thereafter, not losing sight of these patients. Only by systematic series of protracted observations will it be possible to form a correct judgment in regard to the comparative merits of operative and medical measures. There is nothing on record to date giving long enough study of the medical cases for anything like a just appreciation. He begs that practitioners and institutions will keep a register of all patients with exophthalmic goiter and supervise the condition at regular intervals thereafter, even when all is apparently well with them.

114. Treatment of Obesity.—Sternberg's suggestions for improving the traditional routine in the matter of diet have been frequently mentioned in these columns. He here asserts that the subjective phase of dietetics has been neglected altogether too much in the past. It deserves special attention in the dietetic treatment of obesity, particularly measures to reduce the appetite. It is a familiar fact that candy and other sweets taken between meals or just before a meal spoil the appetite for everything except more sweets. Coffee has also a pronounced effect in reducing the appetite, making the individual feel that he has eaten sufficiently. Tradition utilizes these properties by permitting sweets and coffee only at the end of a hearty meal, but in the obese this practice should be reversed. The sweets and the coffee should be taken first, and they will enable the individual to feel satisfied with a much smaller meal than otherwise his appetite would call for. He suggests that mannite is particularly useful for the sweets in cases of obesity, as it has a laxative action. He quotes Pliny to show that the action of sweets in reducing the craving for food was known in ancient times, licorice being recommended to relieve hunger and thirst This, Steinberg says, is the more important, as sugar was not known to Pliny, and honey and licorice were about the only sweets known Alcohol seems to have the opposite effect to coffee and sweets in this respect, as it stimulates the appetite Drugs to deaden the sensibility of the tongue also have an inhibiting action on the appetite He questioned the employees in chocolate factories and found that all were unanimous in saying that if they nibbled or tasted chocolate not long before dinner they spoiled their appetite for the meal The data cited are useful hints in treatment of the obese, as also from the opposite standpoint for individuals whose appetite needs fostering

115 **Principles in the Treatment of Hernia**—Karewski discusses the general principles and the special indications emphasizing in particular the importance of examining all the points where hernia is possible in every case of violent abdominal pain, vomiting and tympanites for which no other cause is apparent as an unsuspected hernia may be the cause of the mischief not forgetting the obturator foramen and the sacrosciatic notch.

123 **Operative Treatment of Hypophysis Tumors**—Schmiegelow summarizes the literature to date on the transnasal removal of hypophysis tumors, including West's contribution to the subject and thirteen cases that have been reported by Eiselsberg, Hochenegg, Kocher and others He then reports a case from his own experience, the patient was a woman of 27 healthy until puberty, when acromegaly developed At the age of 23 she began to have headache gradually becoming accompanied by complete atrophy of the right optic nerve Trouble was beginning in the left eye. when the cystic tumor in the hypophysis was successfully removed by the transnasal route The headache ceased at once and vision in the left eye returned to normal All was proceeding favorably until three weeks after the operation. when acute edema of the brain developed, proving rapidly fatal Kocher has had a similar experience his patient, a woman of 30, dying suddenly four weeks after the operation, and Schloffer also lost a patient from this cause nearly three months after the successful operation The pressure of the tumor on the veins in the base of the brain had evidently compromised the circulation in the region and in the brain generally In Schmiegelow's case and in a number on record the temperature ran up very high as the acute edema developed in the brain and a fulminating meningitis was suspected, but the meninges were found comparatively intact. The rise in temperature is probably the result of irritation of the thalamus from the mechanical compression His patient died too soon for any marked influence on the acromegaly to be apparent, but during the last week she had commented on the improvement in her hands In conclusion, Schmiegelow calls attention to the invaluable service rendered by peroral intubation during the hour and a half long operation The tube was introduced after the patient was under the influence of ether The anesthesia was then continued with chloroform. The intubation permitted the throat around the tube and the mouth to be packed with sponges while respiration proceeded regularly and amply, there was no tendency to cough or vomit and the hemorrhage was minimal

ENTEROPTOSIS IN CHILDREN *

WILLIAM J. BUTLER, M.D.
CHICAGO

The term "enteroptosis," as commonly used, refers to a sinking of the abdominal viscera below their normal positions. Prior to Glénard's communication on this subject displacements of the abdominal organs had formed the subject of numerous contributions. Since that time the literature has grown to an enormous extent, but deals altogether with enteroptosis in the adult. Isolated reports of nephroptosis occurring in children are to be found in the literature, but apparently the subject in general has not received any consideration from pediatrists. Albu, however, included in a paper on enteroptosis a chapter on children. Thanks to the writings of Stiller, Mathes, Richard R. Smith, and others, it is now generally recognized by those interested in this work that the local displacements of the abdominal organs are manifestations of a general status to which the term "habitus enteroptoticus" is applied. This habitus may be recognized by virtue of a body-form characteristic of this class of individuals. It is regarded as a congenital and hereditary anomaly and not as an acquired defect.

If we accept this view of enteroptosis it is self-evident that we should be able to trace this habitus into childhood and even into infancy. An investigation as to the occurrence of this habitus in children is not only indicated but actually necessary for the establishment of the above conception. On the other hand, if it can be shown that this constitutional tendency is the result of conditions occurring subsequent to birth, such as nutritional diseases, etc., it may be possible through prophylactic measures to obviate its development. We occasionally see adults not presenting this habitus who are the subjects of enteroptosis due to bad hygiene, chiefly in child-bearing, but the enteroptosis never attains a high degree, in these cases, in contrast to the congenital type in which the displacements may attain the extreme. In this paper cases of the acquired type will be excluded.

It is necessary for us to have a clear conception of this body form which may be gained from the following description. It is the general make-up of the individual that decides whether he or she belongs to this group. While this habitus is more frequent in females it is often seen in males. Such individuals are slender, of frail bony structure, thin musculature and have little adipose tissue; the chest is long and narrow with small upper and lower apertures. Occasionally the chest is comparatively broad but very shallow. The lower ribs are more or less vertical in direction and the epigastric angle is narrow. The tenth rib may or may not fluctuate; a floating tenth rib is rare. The abdomen is usually flat with occasionally slight bulging below the umbilicus, while sometimes the lower part of the abdomen may be prominent. Becker and Lenhoff studied the body forms of a number of women in the hope of reducing the recognition of the habitus enteroptoticus to a mathematical certainty. As a result of their investigation they stated that if the jugulo-pubic index, obtained by dividing the jugulo-pubic measurement by that of the circumference of the chest at the waist line and multiplying the result by 100, equals or exceeds 77, the individual belongs to the enteroptotic group and will be found to have a palpable kidney. This index may be 77 or higher, but not infrequently it is below this figure. The lumbar lordosis is usually less marked than normal. The foot is more or less flattened. The individuals presenting such a picture will, in a large number of cases, present some evidence of visceral ptosis as well.

Stiller holds a fluctuating or floating tenth rib as a sign of hypoplasia of the thorax and considers an individual with such a rib as of the enteroptotic type which he also regards as synonymous with the habitus neurasthenicus. While we all recognize that many of the enteroptotic habit may present one or both of these stigmata, there are many people of the same type who do not show either one. There is no index or sign that is pathognomonic of this habitus. In fact, adherence to such points in the study of this subject interferes with a clear conception of it. In other words, as above stated, it is the whole makeup of the individual and no one point that decides the classification.

Before taking up the results of an inquiry into the occurrence of enteroptosis in children we should recall some points in the body form of the infant and also of the child up to puberty. We are all familiar with the large head, the short and not very thick neck, the short thorax and comparatively large lower aperture, the short middle zone of the trunk, and the large abdomen of the infant. When we examine the abdomen we invariably find the lower edge of the liver palpable, not infrequently extending close to the navel. The reasons for this are not to be sought alone in the relatively large size of the liver, but also in the comparatively short middle zone of the trunk. The middle zone is the space bounded above by the diaphragm and laterally by the costal arches. As the costal arches at this time are very short they do not cover well the organs of the upper part of the abdomen. The right kidney is frequently palpable practically throughout its whole extent, and occasionally the left is to be felt. It is impracticable to outline the stomach and colon satisfactorily unless we resort to the bismuth meal and x-ray, or distend the stomach with gas. The peculiarities mentioned may be found in the

---

* Chairman's address in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

normal infant and therefore, cannot be looked on as evidence of enteroptosis.

In the growth and development of the infant's body, the middle zone increases in length so that the costal arch extends over the liver until the edge of the latter is felt at or a little below the border of the ribs. Later we are likewise unable to palpate the kidney, and what Albu refers to as enteroptosis of the new-born disappears by the normal growth and development of the infant. In the first months of life in a healthy, breast-fed infant we rarely see any suggestion of the enteroptotic habit. On the other hand, in the frail bodies of infants suffering from various degrees of malnutrition we often see many of its characteristics, to such an extent, in fact that one might think at this early time that one recognized in them the future subjects of enteroptosis. If it could be established that the enteroptotic habit had its foundation in periods of malnutrition which result from nutritional or other diseases, it would furnish us with important information as to the etiology; but I have not been able to establish this.

In older children conditions are somewhat different. Before discussing my results of the examination of the latter I wish to call attention to Stratz' observations on the growing periods of children. He enumerates four such periods: 1. A first period of fulness, from infancy up to the fifth year. 2. A first period of stretching out or elongation, extending from the fifth to the eighth year. 3. A second period of fulness, from the eighth to the eleventh year. 4. A second period of stretching out, from the eleventh to the fourteenth year. In the periods of fulness, the rounding out of the body predominates over the gain in height and *vice versa*, in the periods of stretching out, the gain in height predominates over the rounding out. In the course of my investigations into the existence of the habitus enteroptoticus and the displacements of the abdominal organs I examined from 300 to 400 children. The majority of them were healthy. A small number were dispensary patients with minor disorders. Accurate data were kept of only 155 children between the ages of 6 and 14 years. The history of each child as to past diseases, nutritional disturbances, etc., so far as practicable, was taken. Every child received a careful physical examination in which the following points were noted: Condition of nutrition, musculature, bony structure, especially with reference to spine and thorax, form and development of the latter, direction of the lower ribs, the epigastric angle, the mobility of the tenth rib, the jugulo-pubic and thoracic measurements, contour of the abdomen, pedal arch, etc. Thorough examination of the abdomen for organ displacements was

made. The stomach of each child was inflated with carbon dioxid made by using sodium bicarbonate and tartaric acid. A simple means of determining the lower border of the distended stomach is to rub the hand quickly downward from the xiphoid cartilage. The difference in tension on leaving the stomach is immediately perceived. The line at which the change is noted will mark the lower border. Sometimes the outline of the distended stomach is evident on inspection.

Fig. 5.—Girl of 14 years, showing the enteroptotic habit, but without downward displacement of abdominal organs

Fig 6 —Girl of 12 years, lacking many of the characteristics of the enteroptotic habit, but having nephroptosis and neurasthenic symptoms

Early in this work it became evident that no one sign, such as a fluctuating tenth rib, a narrow epigastric angle, or a high index, could be depended on to decide the existence of the habitus enteroptoticus in a child at any age. Only by keeping in mind the general picture of this condition could a correct judgment be reached. Fully 50 per cent. of all children have a movable tenth rib. It is rarely found unattached to the costal arch so as to deserve the designation floating. Some children with a narrow chest, a sharp epigastric angle, and a typical habitus asthenicus, have a firmly fixed tenth rib. A broad epigastric angle is frequently found in children as the result of flaring of the ribs due to an early rachitis, and yet children with such an angle may present the general make-up of this habitus. The above description of the habitus enteroptoticus as seen in the adult is not often seen in its entirety in very young children; yet we often see, even in the first years of life, children of such frail structures and atonic condition that they might be properly grouped in this class. On the other hand, in late childhood, corresponding to the second elongation period of Stratz, at the approach of and with the development of puberty, fully one-third of the females and about one-sixth of the males exhibit the characteristic habitus enteroptoticus.

The following are results of the examination of 155 children, 50 girls and 105 boys: The edge of the liver was palpable in the nipple line in 35 of the girls either at the border of the ribs or one or two finger's breadths below it on inspiration. The same condition was found in 82 boys. The right kidney was dislocated downward in three girls, in one of whom it was also displaced forward and palpable throughout. In six others the lower pole of the right kidney was palpable on deep inspiration. In one boy the right kidney was dislocated and palpable throughout its extent. In five others the lower pole of the right kidney only was palpable on deep inspiration. In 40 per cent. of the children examined the lower border of the stomach distended with gas extended to or within a half inch of the umbilicus. The position of the stomach was determined in several girls by means of the *x*-ray, a bismuth meal being given and a skiagraph taken immediately afterward. Three of the girls, two of whom had a dislocated right kidney and one a right kidney palpable for half its extent, showed the lower border of the stomach below the umbilicus. The ages of the first two were respectively 14 and 12 years and that of the third 12 years. In the vast majority of children throughout infancy and childhood the edge of the liver can be palpated in inspiration at or below the costal arch; and even when it is felt the width of two or three fingers below the costal arch we are not justified in assuming hepatoptosis. It will be noted that in three girls and in only one boy a right-sided nephroptosis was found. These children were 12 or more years of age. In several children of all ages the lower pole of the right kidney was apparently palpable on deep inspiration. Too great stress must not be laid on this fact, for on account of the difficulty of the examination the possibility of error is considerable. In no case was the left kidney palpable. In the three girls above mentioned the habitus enteroptoticus, as well as the displacement of the abdominal organs, was well marked.

During my examination of the children I inquired as far as practicable into the condition of their nutrition during infancy and early childhood with the view of learning if possible whether disturbances of nutrition might have some bearing on their future development. It seems quite possible that infants who suffer from malnutrition, marasmus, rachitis, etc., may undergo a greater or less degree of underdevelopment in all tissues and that they may ultimately rank in the enteroptosis class. Likewise prolonged periods of low nutrition at any stage of child life might form a foundation for the development of this abnormality. For reasons quite apparent an accurate history of the conditions in early childhood was seldom obtainable. On account of the unsatisfactory results of this inquiry a close relation between early nutritional disease and the enteroptotic habit could not be clearly made out in many instances. We usually find, however, that the older chidren in whom this condition is present have always been undernourished and present a greater or less degree of underdevelopment.

From my own observations I am convinced that the evidences of the enteroptotic habit are observable throughout childhood, but in more pronounced form in late childhood approaching and in the period of puberty. In the first days of life palpable kidneys and liver are not to be regarded as signs of enteroptosis as these findings are common at this period of life. Beyond the first year and up to late childhood palpable kidneys and displaced stomachs are exceptional although signs of this habitus were evident in some of the children examined. On the other hand, coinciding with the development of the adult type of this habitus with the approach and in the period of puberty the displacement of the abdominal viscera become less exceptional: in fact, the actual ptoses, I believe, are practically first seen at the period of puberty.

THE APPROXIMATION OF WIDELY SEPARATED WOUND MARGINS

JOSEPH RILUS EASTMAN, M.D.
INDIANAPOLIS

In the closure of wounds, the margins of which are widely separated, as in those in which there is an extensive skin defect, sutures which will bring together the wound edges, or skin margins, and hold them coapted, resisting the sometimes unavoidable tension without cutting out, are obviously helpful.

For the purpose of relaxing the tissues immediately along the wound margin heavy interrupted sutures are usually passed at a distance of one inch or more from the wound line on each side, and these, to some extent, take the strain from the coaptation sutures.

Such relaxation sutures, however, do not differ essentially from the coaptation sutures applied closely along the wound margin. Their slight advantage consists in the fact that they are usually of heavier material and, passing through the skin at a greater distance from the wound, the likelihood of their cutting out is lessened, since they may cut for a considerable distance without splitting the skin quite to the wound edge.

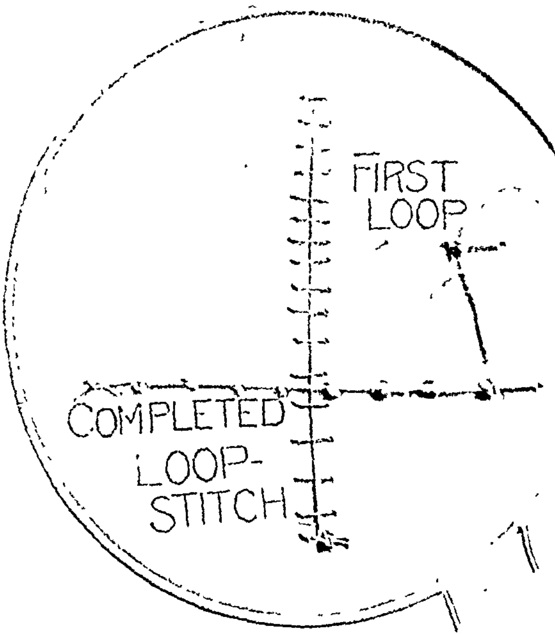

Fig. 1.—Manikin to show running loop relaxation suture crossing breast amputation wound line. Tension is on ten points instead of two.

Such relaxation sutures, while they doubtless possess some value, are often unsatisfactory if the retraction on the edges of the wound be great.

The ingenious running suture employed by Charles Mayo after breast amputations, in which the wound margins must be brought together under tension, is at once a coaptation and a relaxation suture. The manner of its application and its usefulness are well known.

This continuous suture is open to the objections applying to other continuous sutures. If the continuous suture breaks at any point the wound margins must fall apart, unless the closure is otherwise reinforced. Here dependence is placed on a single strand. Infection, if it should occur, tends to travel along a continuous suture. These perhaps somewhat captious objections do not apply so clearly to interrupted sutures.

By most surgeons it is felt that accurate approximation of wound edges, particularly after operations for malignant disease, is very desirable. Until more is known of the origin and nature of cancer, the lurking possibilities of a granulating surface with its embryonal cell elements will occasion uneasiness until healed over. Even skin grafts with their active cell proliferation can hardly have the confidence which is given to normal skin. The practice of approximating the wound edges by separating the skin from its attachments over a large area with consequent diminution of blood-supply is not infrequently followed by sloughing, which greatly increases the difficulties which militate against primary covering of the defect.

Clearly it should be the maxim of every surgeon to have no thought of the covering of the defect while engaged in the radical removal of every vestige of malignant or suspected tissue. The manner of repairing the defect is a matter of no importance until the operation proper is complete. When a thorough operation, however, has been completed, at least a part of the defect can always be covered by precise coaptation of wound margins without unsafe tension.

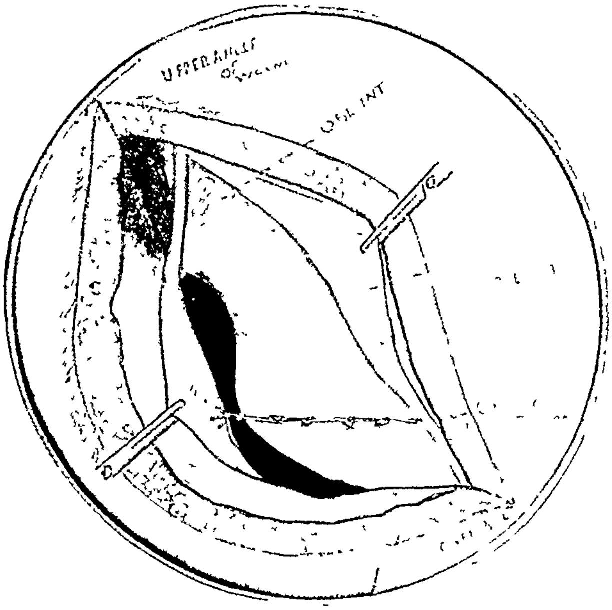

Fig. 2.—Manikin showing use of running loop relaxation suture in drawing the obliquus internus and transversalis and conjoined tendon to Poupart's ligament in wide inguinal hernias, likelihood of splitting being lessened by distribution of tension over several points.

The running-loop suture shown in Figure 1 holds the margins together more firmly than any relaxation suture with which I am familiar; moreover, it will not cut out unless the pull be very great indeed, for here the tension is distributed over many points instead of two, as in the case of the ordinary relaxation sutures. In the case of the running-loop suture shown on the manikin in Figure 1 there are ten loops; therefore the tension is divided among ten points, and if several sutures of this character be used to reinforce the coaptation sutures, the wound margins, for example after a breast amputation, may be brought together under tension without subsequent separation and without cutting out of the sutures.

In breast surgery these relaxation sutures can be applied best after the wound edges have been coapted in the customary manner. They are introduced in much the same manner as a seamstress introduces the "chain-stitch," but differ from the chain stitch in that each loop is secured by a "hard" knot before the next loop is taken.

Beginning about two and one-half inches from the wound margin the needle is passed under the skin in the direction of the wound edge and brought out about 1 cm. nearer the wound edge than it entered. The long suture is drawn through to a point near its middle and tied with a reef or hard knot, as if one were tying off a blood-vessel, the knot falling over the aperture of exit or the opening nearer the wound line. In other words, the suture is passed under the skin for 1 cm. and both ends are tied over the opening next to the wound. The needle is then passed back through the hole under the knot for the second loop and the long ends are tied again over the opening at which the needle emerges. The loops are carried across the wound line and as many are taken on the opposite side as the tension which is to be overcome makes necessary.

It is my practice to apply several such chain sutures after breast amputations if there is considerable traction on the coaptation sutures. Three, about one inch apart, placed where the traction is usually greatest, that is, near the middle of the wound line, usually suffice.

This chain suture may be utilized in drawing the internal oblique and transversalis muscles to Poupart's ligament in cases of very wide inguinal hernia. Likewise the conjoined tendon may be drawn and held to Poupart's ligament if several loops of the chain-stitch be applied across it. Wheras an ordinary suture in hernia with wide separation often simply splits off a narrow ribbon from the edge where the needle perforates the internal oblique and transversalis muscles, the chain suture will pull over the whole muscle mass without injury.

The splitting of the conjoined tendon for the purpose of relaxation, and the division of the rectus sheath with or without transplantation of the belly of the rectus, while they are helpful practices in some cases, may be dispensed with often, if the chain suture here described be used.

331 North Delaware Street.

TUMOR OF THE SPINAL CORD

HERBERT C. MOFFITT, M.D., AND HARRY M. SHERMAN, M.D.

SAN FRANCISCO

Although the literature on spinal tumors has been enriched by numbers of excellent observations in the past three or four years, it is still worth while to record carefully studied cases.

REPORT OF CASE

History.—A woman aged 33, a native of Scotland, entered the University of California Hospital Feb. 2, 1910. She had been very delicate as a child but since then unusually well, apart from frequent attacks of tonsillitis. Three years previously she was thrown from a buggy and fell on her back but was not confined to bed and had no pain afterward. The present trouble began in October, 1908, when she would be awakened regularly about 4 a. m. with pain across the back, just above the level of the iliac crests. This was not very severe, did not radiate and disappeared as soon as she got out of bed. About the beginning of 1909 the pain disappeared and she felt very well until one day in spring—about March—she jumped down three feet from a porch. Right after this the pain in the back returned and she began to have pain in the lower abdomen, on both sides alike, running diagonally downward from the rib border to the pubes. This pain was not severe and disappeared in a few weeks. In July, 1909, she noticed lameness and stiffness in the left leg. Disturbance of sensation was not noted, but, after a fall, painless ulcers developed below the left knee and were weeks in healing. Both legs were awkward and she fell frequently, finding it difficult to keep her balance. After taking electrical treatment in October, 1909, there had been frequent incontinence of urine and feces. Since November there had been rapidly increasing weakness and stiffness of the left leg and frequent pain down the front of the left thigh. Weakness and rigidity of the right leg had been noted only a week before entrance and walking had become almost impossible. The patient's family history was excellent. There was nothing to suggest syphilis.

Examination.—The important nervous signs were as follows:

1. An ataxic paraplegia that on entrance rendered standing or walking very difficult and two weeks later impossible. Rigidity and ataxia interfered with walking more than loss of power; there never was complete loss of power in any muscle-groups, though the left lower extremity was much weaker than the right. Rigidity was much greater on the left; there was bilateral pes equinus, more pronounced on the left.

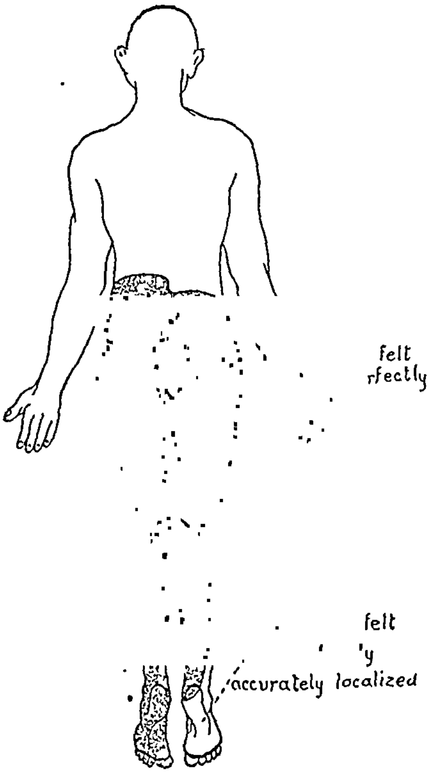

Fig. 1.—Diagram of modifications in sensation, posteriorly; dark portion represents anesthetic area

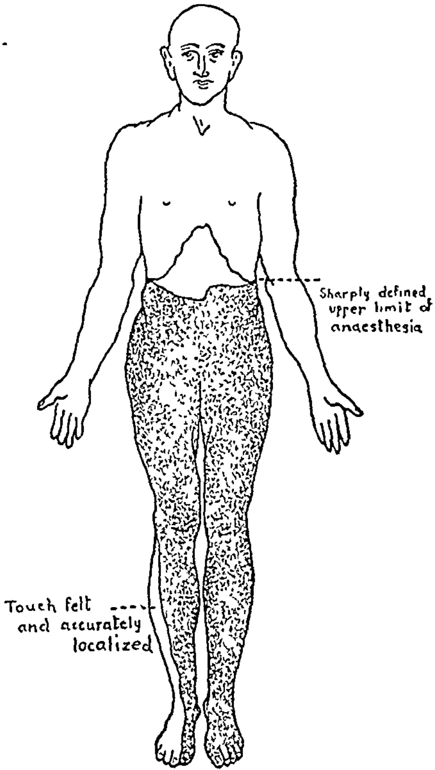

Sharply defined upper limit of anaesthesia
Touch felt and accurately localized

Fig. 2.—Diagram of modifications in sensation anteriorly.

2. Sensation varied somewhat during the three weeks of observation and the chart represents the final examination of sensation to touch just before the operation. There was absolute loss of pressure sense, sense of position and of passive movement in the entire left lower extremity and in the right foot and leg. Analgesia and loss of temperature-sense followed accurately the distribution of anesthesia except toward the upper limit; in the zone between the umbilicus and the pubes the loss was not complete and, as has been noted by others, anesthesia gave much more accurate information as to the level of the lesion.

3. Reflexes in the lower extremities were much increased, although rigidity interfered with the demonstration of clonus. The Babinski and Oppenheim phenomena were present on both sides. The upper abdominal reflexes were present, the reflex on the right being much livelier than on the left. The lower abdominal reflexes were not obtained. The umbilicus was in the median line. The muscles on the left side just above and below the umbilical level reacted decidedly less to the faradic current than on the right. There was occasional incontinence of urine.

4. There was moderate tenderness of the ninth, tenth, eleventh and twelfth dorsal vertebræ at times, and the spine in this region was slightly rigid. On sitting there was a slight scoliosis with convexity toward the left in the lower dorsal spine but this disappeared on standing.

5. Trophic changes were limited to the old scars below the left knee, and to a decided edema of both legs. Any movement caused sudden shooting pains down the anterior part of the thigh and leg, and severe pain occurred at times beneath the left costal arch and in the left groin.

The Wassermann reaction was negative. On February 12 hypodermic injection of 2 mg. of old tuberculin was followed in twelve hours by a typical rise of temperature, general malaise and decided increase of tenderness and pain in the back.

Diagnosis.—The level of the lesion in the cord could readily be deduced from the characteristic sensory changes. Following Sherrington's teaching, it is to be remembered that complete loss of *common sensation in the ninth* dorsal segment must mean involvement of the eighth dorsal segment as well. It is not here the place to go into the differential diagnosis of the lesion. The onset with nerve-root pain, the gradual development of paraplegia, the predominance of the symptoms on the left side, the early and marked ataxia led to the diagnosis of an intraspinal tumor or a localized meningitis rather than vertebral disease. Despite the general and local symptoms following the injection of tuberculin, the absence of definite vertebral changes spoke strongly against a tuberculous process, and the reaction was referred to slight signs of old thickening at the left apex. Oppenheim has recently emphasized the necessity of caution in judging that a nerve lesion is tuberculous simply from a pronounced tuberculin reaction.

In the absence of any results after three weeks' treatment with the large doses of mercury and iodid, the patient was referred to Dr. Sherman with the advice to cut down on the cord opposite the sixth dorsal spine. From the mode of onset the tumor would probably lie on the left posterior part of the cord. The following is Dr. Sherman's account of the operation:

Operation and Course.—"The relatively brief examination I made of the patient led me to the conclusion arrived at by Dr. Moffitt and I wholly agreed in the opinion that the spinal canal should be opened. I did, therefore, a simple laminectomy to the exclusion of an osteoplastic operation. The simple operation preserves the continuity of the erector spinæ muscles, an important point in the convex curve of the dorsal spine, as it is a safeguard against consequent kyphosis, which might easily follow the cross-section of the muscles and the loss of their motor nerves, both of which are necessitated in the osteoplastic method. As much as possible of the periosteum of the laminæ was preserved, but the patient was a stout woman, the spinal muscles were massive and lay beneath a thick fatty panniculus, so that the detailed scraping of the periosteum from each lamina was physically difficult. The laminæ and spinous processes were removed from the sixth, seventh, eighth and ninth vertebræ. This exposed the dura, and as it did not pulsate and it seemed likely that more room might be needed, the lamina and spine of the fifth vertebra also were removed. The dura was tense but opposite the sixth body a mass was felt and could now be seen. When the dura was incised there was folded back with the left half a small tumor 1.5 cm. by 0.75 cm. adherent to the dura. The cord was at this point dislocated slightly to the right, so that it made a little curve in its course, but the surface showed no indentation from the pressure of the tumor. The tumor was readily detached from the dura, the little hemorrhage which followed stopping easily on a little pressure. When the cord itself was exposed it was seen to be pulsating normally, the hypertension of the cerebrospinal fluid probably having obscured the pulsation in the intact dura.

"After the removal of the tumor the dura was caught together with three catgut sutures, the muscles were sutured together across the median line over it and the skin sutured. The patient was put into a dorsal semi-jacket of plaster of Paris so padded that no pressure could come on the suture line.

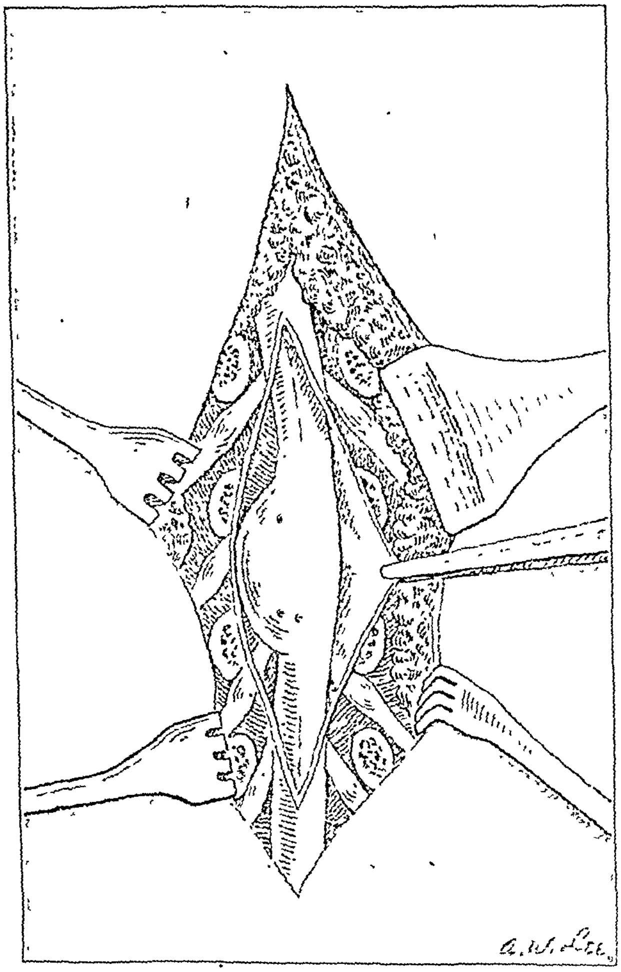

Fig. 3.—Tumor of spinal cord (small spindle-cell sarcoma) opposite sixth dorsal vertebra.

"Healing was normal. On the twenty-fifth day the patient sat up in bed; on the twenty-seventh day she was up in a wheel chair and on the thirty-first day she walked.

"In the pia mater were seen three small, flat, white specks, 2 to 3 mm. in diameter; these were clipped out and sent to the laboratory with the tumor."

Macroscopic Examination of Specimen.—Dr. A. W. Lee returned the following report: "The tumor was oval in shape with one end slightly pointed. It measured about 2 by 1 cm., was of whitish-pink color, rather firm to the touch and showed on gross section a somewhat bulging cut surface that presented an intricate pattern of small whorls. Weight 1,600 mg. The bodies from the pia mater were grayish-white in color, irregular in shape, firm to the touch and measured approximately 2 by 2 mm. Some pieces of tumor were fixed in alcohol, others in Orth's fluid; the same fixation methods were employed with the bodies from the pia. The preparations were sectioned in celloidin and stained with hematoxylin and eosin."

Microscopic Findings.—"The major portion of the tumor consists of small spindle-cells arranged in whorls. Here and there, however, irregular groups of round-cells appear. Both of these cellular elements show nuclei of a light staining index and but little protoplasm. Occasionally mitotic figures are found among them. Most of the larger blood-vessels are involved to an extreme degree in hyaline degeneration, and in a few areas hyalomyxomatous changes are found irrespective of the blood-vessels. Small interstitial hemorrhages occur but do not form a prominent feature of the picture. The small bodies from the pia consist of ramifying columns of hyaline tissue which histologically do not seem to bear any direct relationship to the tumor: Small spindle-cell sarcoma."

Post-Operative History.—The day following operation sensation to touch had returned to a considerable extent in both limbs and the patient could localize a touch fairly well. Two days later rigidity was much less and the knee-jerks and ankle-jerks were not much increased. A Babinski was obtained on the left but not on the right side. Movements of the toes were correctly interpreted. It was interesting at this time to note that pain and heat and cold were felt much better on the left than on the right side. All movements could be executed with fair strength. Edema quickly disappeared. Bladder control was soon established. During the first month after operation signs varied considerably; the improvement was not steady but marked by retrogressions in which sensation below the knees would be less acute and weakness of both extremities often quite decided. Gradually such periods became less frequent and less marked and the patient was able to stand and walk on the thirty-first day. For a few weeks the gait was decidedly ataxic paraplegic, and there was complaint of stiffness and soreness in the lower dorsal and lumbar spine.

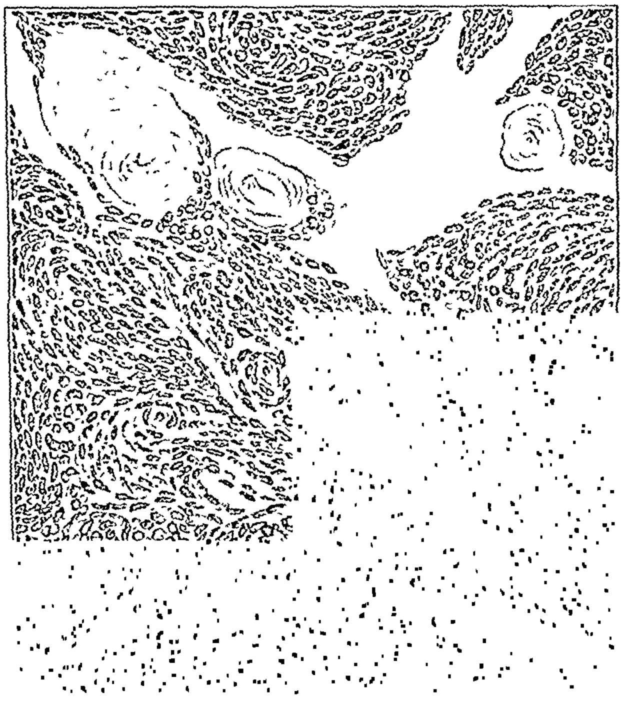

Fig 4.—Histologic structure of tumor, consisting of small spindle-cells arranged in whorls, with irregular groups of round-cells. The blood-vessels show hyaline and myxomatous degeneration.

When seen last, Sept. 2, 1910, the patient felt perfectly well, had no difficulty in walking, no weakness, no pain or paresthesias. The knee-jerks were moderately increased, and sensation, superficial and deep, was entirely normal.

240 Stockton Street.

interruption of the blood-supply of the kidney has on its parenchyma.

Our investigation was undertaken to observe how long the circulation through the renal vessels can be completely obstructed, without causing permanent degenerative changes in the kidney. This question is not only of interest to the pathologist, but is of even greater importance to those surgeons who believe in employing one of the various methods of compressing the renal vessels to control hemorrhage during operations like nephrotomy, for the removal of calculi, etc. It is beyond the scope of this paper to discuss which particular method of compression is preferable clinically, whether by clamp, rubber ligature or the fingers.

2. HISTORY

A review of the literature shows that but little work on this subject has been reported, since Litten[3] published his exhaustive article on hemorrhagic infarct in 1880. His observations and deductions will be referred to later. He found that ligation of one and a half to two hours was enough to show all changes, and that these changes are only more intensive but not greater in extent if the ligature is left on longer, i. e., three or four hours.

A considerable amount of experimental work has been done during the past ten years to study the effect of permanent ligation, first, of both renal artery and vein;[4, 5] second, of these vessels separately,[4] and, third, of the ureter.[6] It is now generally accepted that these three varieties of permanent ligation cause necrosis with secondary atrophy of the kidney; hence it will be unnecessary to consider the various articles which deal with permanent ligation, since the object of our experiments was simply to determine the effect of temporary anemia.

Beattie and Dickson[7] state that, since the appearance of Litten's paper, similar experiments on permanent ligation of the renal artery were repeated by George Mackay, in Berlin, and the specimens were examined by Professor Greenfield, and that, more recently, one of the writers closely observed an extended series of similar experiments and observations conducted by Dr. Duncan Forbes, in the Pathological Department of the University of Edinburgh, under the direction of Professor Greenfield. Although these experiments dealt with permanent ligation, the animals were killed at varying periods after the application of the ligature, some almost immediately after ligation, others two hours after the ligature was applied. Dr. Forbes' findings, two hours after the ligature was applied, agree with our findings in a similar experiment.

A few observations have been made on the effects of temporary obstruction of the renal veins by Carrel.[8] Guthrie[9] reports one experiment in which the arterial circulation was restrained for nearly ten minutes. He found that this short temporary anemia alone (that is, without perfusion) caused no marked alterations. Aside from this work of Guthrie and that of Litten, we have been unable to find any experiments similar to those reported in this paper.

3. PLAN OF PROCEDURE AND TECHNIC

1. In order to study the permanent effects of temporary compression of the renal vessels the problem was attacked in the following manner: Five experiments were performed, the renal vessels being clamped for fifteen, thirty, forty-five, sixty and ninety minutes, respectively. At the end of this time the clamp was removed, allowing the circulation to be reestablished, as would be the case clinically, after nephrotomy. Rabbits of average size were used and the left renal vessels compressed in all of the experiments. Ether was used as an anesthetic.

The kidney was brought up into a median incision in the abdominal wall and the renal vessels were isolated and compressed with a rubber-covered clamp or serrefine. In every experiment the portion of artery between the clamp and the kidney was palpated, to be sure there was no pulsation, that is, that the obstruction was complete. In several cases a second clamp was applied, to be more certain that the obstruction was complete. The kidney and pedicle, with the clamp applied, were then returned to the left side of the abdomen, as near its original position as possible, and the peritoneal cavity temporarily closed by apposing the peritoneal edges. The clamp was allowed to remain on the vessels for variable periods: in Experiment 1, for fifteen minutes; in Experiment 2, for thirty minutes; in Experiment 3, for forty-five minutes; in Experiment 4, for sixty minutes; in Experiment 5, for ninety minutes. Four weeks after each one of these experiments the animal was killed with ether, and both kidneys were removed for histologic study and immediately placed in fixing solutions.

2. In order to study the immediate changes produced two experiments were performed. In one experiment the vessels were compressed for two hours, and at the end of this time the kidney was removed and histologic sections made at once. In the second the vessels were compressed for two hours and the kidney removed forty-eight hours after the operation.

4. CLINICAL RESULTS

No attempt was made to note the immediate and later effects of these experiments on the secretion of urine, either as to composition or amount. Only the resulting histologic changes were studied. In general, the animals appeared normal after the operation.

5. ANATOMIC RESULTS

I. GROSS EXAMINATIONS

After the clamp had been applied for the required length of time, and when the kidney was exposed to remove the clamp, the kidney was seen to be congested and cyanotic, and was larger than normal. In the experiments, in which compression lasted an hour and a half and two hours, these changes were especially marked, the kidney being dark blue and greatly increased in size.

When the kidneys were examined four weeks after the compression, they appeared quite different. In the experiment of compression for an hour and a half, the left (compressed) kidney was seen to be distinctly smaller than the right, and was much paler in color, that is, the kidney was atrophic and showed macroscopic evidence of marked parenchymatous degeneration. The cut surface showed that this parenchymatous degeneration was especially of the cortex. In the experiments in which the compression had been less than one hour and a half, there

THE EFFECT ON THE KIDNEY OF TEMPORARY COMPRESSION OF ITS VESSELS *

D. N. EISENDRATH, M.D., AND D. C. STRAUSS, M.D.
CHICAGO

1. PURPOSE

Considerable difference of opinion exists among surgeons in regard to the advisability of compressing the renal vessels to control hemorrhage during nephrotomy. Some maintain that in addition to the temporary functional disturbance,[1, 2] which often follows such compression, the anemia so produced causes serious and permanent degenerative changes of the parenchyma. At a recent meeting of the Chicago Urological Society Dr. A. D. Bevan stated that it would be of considerable interest to observe experimentally what effect such temporary

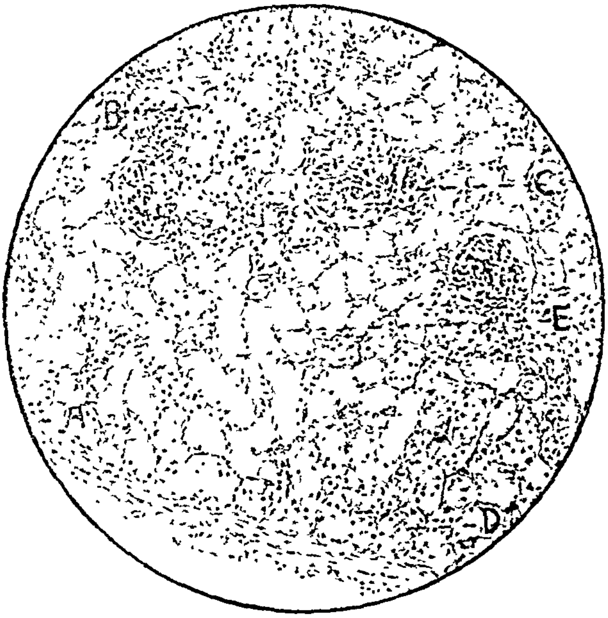

Fig 1.—Section from kidney removed forty-eight hours after two-hour compression of renal vessels (×110). Note the extensive, total coagulation necrosis of the tubular epithelium. Glomerulæ are normal and intact. Interstitial tissue is practically normal except for a few focal hemorrhages not yet absorbed (a) beneath capsule (b) in cortex between the tubules. Some scattered tubules are intact; c, intact tubule showing lumen filled with a hyaline cast; d, tubule showing epithelium partially destroyed but lumen still preserved, but filled with hyaline cast; e, tubule showing total necrosis of the epithelium, which is hyaline and swollen, completely obliterating the lumen.

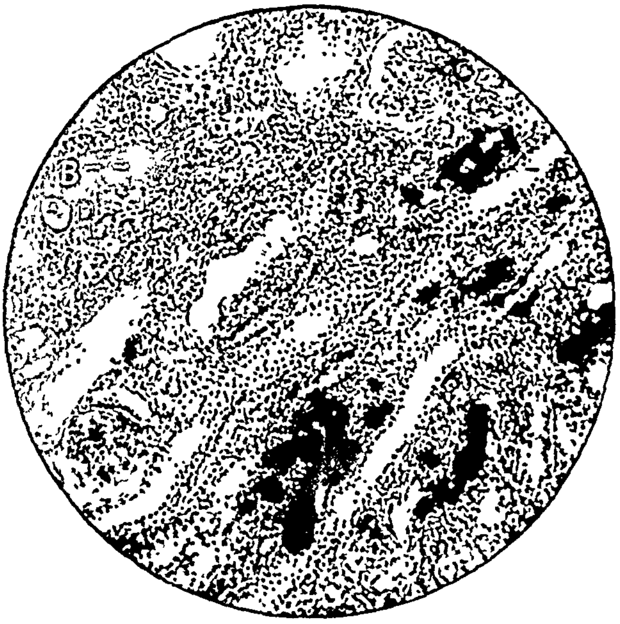

Fig 2.—Section from kidney removed four weeks after 1-hour compression of renal vessels (×110.—Zeiss). Note extensive calcification of tubular epithelium; that this is entirely intratubular; that the glomerulæ, interstitial tissue, and blood vessels remain calcium-free. Calcium deposit (a) in degenerated epithelium is peripherally located, leaving an open lumen; (b) later stage—calcium deposit completely fills tube to form solid plug; c, normal glomerulus; d, hyaline cast in tubule whose epithelium is flattened. Note extensive round-cell interstitial infiltration and parenchymatous degeneration.

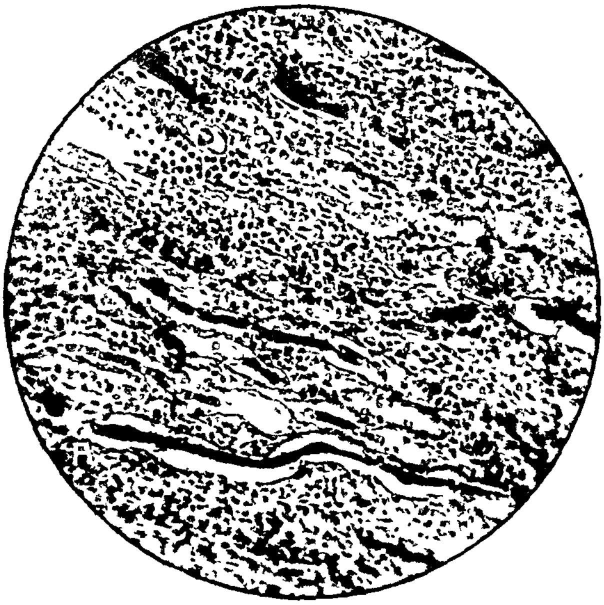

Fig 3.—Section from kidney removed four weeks after 1½-hour compression of renal vessels (×170.—Zeiss). Note extensive deposition of calcium in tubuli recti; a, cylinder of calcium in straight tubule whose epithelium is destroyed. The space between the calcium deposit and the interstitial tissue is due to shrinkage of the tissue in fixing. Note also the extensive round cell interstitial infiltration. A few polynuclear leukocytes can also be seen.

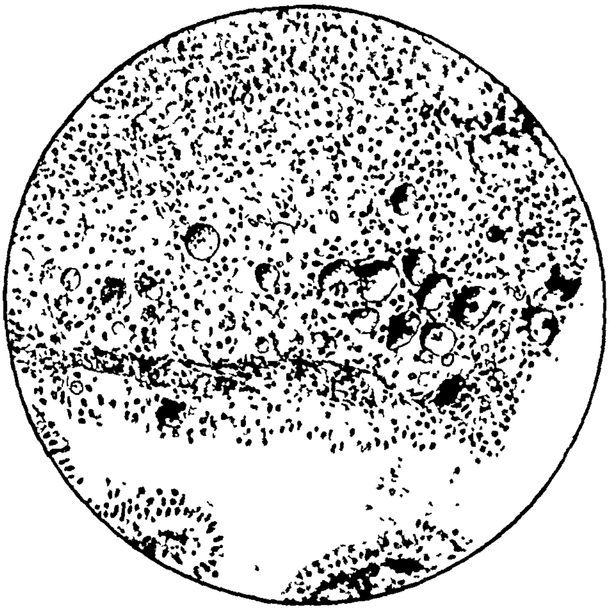

Fig 4.—Section of kidney removed four weeks after 1½-hour compression of renal vessels (×170.—Zeiss). Note peripheral deposit of calcium within excretory tubules, seen in cross section. Note also the marked decrease of interstitial infiltration in this section at the papilla, as compared with that in the region of the tubuli recti (Figure 3).

interruption of the blood-supply of the kidney has on its parenchyma.

Our investigation was undertaken to observe how long the circulation through the renal vessels can be completely obstructed, without causing permanent degenerative changes in the kidney. This question is not only of interest to the pathologist, but is of even greater importance to those surgeons who believe in employing one of the various methods of compressing the renal vessels to control hemorrhage during operations like nephrotomy, for the removal of calculi, etc. It is beyond the scope of this paper to discuss which particular method of compression is preferable clinically, whether by clamp, rubber ligature or the fingers.

2. HISTORY

A review of the literature shows that but little work on this subject has been reported, since Litten[3] published his exhaustive article on hemorrhagic infarct in 1880. His observations and deductions will be referred to later. He found that ligation of one and a half to two hours was enough to show all changes, and that these changes are only more intensive but not greater in extent if the ligature is left on longer, i. e., three or four hours.

A considerable amount of experimental work has been done during the past ten years to study the effect of permanent ligation, first, of both renal artery and vein;[4, 5] second, of these vessels separately,[4] and, third, of the ureter.[6] It is now generally accepted that these three varieties of permanent ligation cause necrosis with secondary atrophy of the kidney; hence it will be unnecessary to consider the various articles which deal with permanent ligation, since the object of our experiments was simply to determine the effect of temporary anemia.

Beattie and Dickson[7] state that, since the appearance of Litten's paper, similar experiments on permanent ligation of the renal artery were repeated by George Mackay, in Berlin, and the specimens were examined by Professor Greenfield, and that, more recently, one of the writers closely observed an extended series of similar experiments and observations conducted by Dr. Duncan Forbes, in the Pathological Department of the University of Edinburgh, under the direction of Professor Greenfield. Although these experiments dealt with permanent ligation, the animals were killed at varying periods after the application of the ligature, some almost immediately after ligation, others two hours after the ligature was applied. Dr. Forbes' findings, two hours after the ligature was applied, agree with our findings in a similar experiment.

A few observations have been made on the effects of temporary obstruction of the renal veins by Carrel.[8] Guthrie[9] reports one experiment in which the arterial circulation was restrained for nearly ten minutes. He found that this short temporary anemia alone (that is, without perfusion) caused no marked alterations. Aside from this work of Guthrie and that of Litten, we have been unable to find any experiments similar to those reported in this paper.

3. PLAN OF PROCEDURE AND TECHNIC

1. In order to study the permanent effects of temporary compression of the renal vessels the problem was attacked in the following manner: Five experiments were performed, the renal vessels being clamped for fifteen, thirty, forty-five, sixty and ninety minutes, respectively. At the end of this time the clamp was removed, allowing the circulation to be reestablished, as would be the case clinically, after nephrotomy. Rabbits of average size were used and the left renal vessels compressed in all of the experiments. Ether was used as an anesthetic.

The kidney was brought up into a median incision in the abdominal wall and the renal vessels were isolated and compressed with a rubber-covered clamp or serrefine. In every experiment the portion of artery between the clamp and the kidney was palpated, to be sure there was no pulsation, that is, that the obstruction was complete. In several cases a second clamp was applied, to be more certain that the obstruction was complete. The kidney and pedicle, with the clamp applied, were then returned to the left side of the abdomen, as near its original position as possible, and the peritoneal cavity temporarily closed by apposing the peritoneal edges. The clamp was allowed to remain on the vessels for variable periods: in Experiment 1, for fifteen minutes; in Experiment 2, for thirty minutes; in Experiment 3, for forty-five minutes; in Experiment 4, for sixty minutes; in Experiment 5, for ninety minutes. Four weeks after each one of these experiments the animal was killed with ether, and both kidneys were removed for histologic study and immediately placed in fixing solutions.

2. In order to study the immediate changes produced two experiments were performed. In one experiment the vessels were compressed for two hours, and at the end of this time the kidney was removed and histologic sections made at once. In the second the vessels were compressed for two hours and the kidney removed forty-eight hours after the operation.

4. CLINICAL RESULTS

No attempt was made to note the immediate and later effects of these experiments on the secretion of urine, either as to composition or amount. Only the resulting histologic changes were studied. In general, the animals appeared normal after the operation.

5. ANATOMIC RESULTS

I. GROSS EXAMINATIONS

After the clamp had been applied for the required length of time, and when the kidney was exposed to remove the clamp, the kidney was seen to be congested and cyanotic, and was larger than normal. In the experiments, in which compression lasted an hour and a half and two hours, these changes were especially marked, the kidney being dark blue and greatly increased in size.

When the kidneys were examined four weeks after the compression, they appeared quite different. In the experiment of compression for an hour and a half, the left (compressed) kidney was seen to be distinctly smaller than the right, and was much paler in color, that is, the kidney was atrophic and showed macroscopic evidence of marked parenchymatous degeneration. The cut surface showed that this parenchymatous degeneration was especially of the cortex. In the experiments in which the compression had been less than one hour and a half, there was no appreciable difference in size between the right and left kidney. In the one-hour experiment, the left kidney was much paler than the right, and the cut surface showed very marked parenchymatous degeneration. In the forty-five-minute experiment, also, the kidney showed considerable gross evidence of parenchymatous degeneration. In the fifteen-minute and the thirty-minute experiments, however, the kidney showed no gross changes.

The cut surface of the kidney which was removed immediately after the two-hour compression showed marked congestion. The cut surface of the kidney which was removed forty-eight hours after the two-hour compression of the renal vessels, also appeared somewhat congested, but this was much less marked.

II. MICROSCOPIC EXAMINATION

For this part of the work we are greatly indebted to Dr. J. W. Jobling, who was kind enough to look over the histologic sections with us.

A. IMMEDIATE CHANGES

1. Two-Hour Compression; Kidney Removed at Once.—Sections from the kidney which was removed immediately after two-hour compression show hemorrhage just beneath and within the capsule, elevating the capsule, and separating its layers. There are numerous focal hemorrhages in the medulla, especially between the tubules near the pelvis. It may be noted that the hemorrhage is from the capillaries which are nearest the collateral blood-supply (that is, ureteral artery to pelvis, and capsular arteries from the lumbar arteries). The glomerular tufts are distended, and the intertubular capillaries are generally greatly distended. The tubular epithelium shows very little change, and the nuclei stain well. In some cases, red blood-cells can be seen in the glomerular space, and *in the tubuli recti.*

2. Two-Hour Compression; Kidney Removed After Forty-Eight Hours.—Sections from this experiment (Fig. 1.) show that the focal hemorrhages which were seen immediately after the two-hour compression have been absorbed to a large extent. Most of the red blood-cells have disappeared from the capsule also. The striking feature in these sections is the marked necrosis of the tubular epithelium. The tubular epithelium, especially of the cortex, is almost entirely destroyed, showing total coagulation necrosis; the nuclei are gone for the most part, the individual cell outlines cannot be made out, and the cells are greatly swollen, so that the epithelium obliterates the lumen in many places, and gives the tubules the appearance of hyaline bands or casts. This total necrosis of the epithelium is very marked in the cortex and decreases in intensity toward the papillæ, where there is practically no change of the epithelial lining, but hyaline blood casts are often seen in the lumen. Although this necrosis of the epithelium is very general, some tubules, in patches, escape, some partially, others almost entirely. Where the tubules are normal, or where a lumen remains, the lumen contains either a serous exudate, or, as a rule, hyaline or blood-casts. These completely fill the lumen, plugging them. The excretory tubules in the medulla contain hyaline and blood-casts, which obstruct their lumen. These are striking. There is but very little interstitial infiltration. The glomeruli appear normal.

B. LATER CHANGES

Four weeks after temporary compression the right kidney, whose vessels had not been compressed, showed no changes, with the exception of a slight amount of round-celled infiltration in some of the cases, and occasional slight parenchymatous changes, as one finds in rabbits generally.

Certain changes were common to all of the left (compressed pedicle) kidneys, such as thickening of the capsule and slight perirenal adhesions.

Experiment 1.—Fifteen-Minute Compression.—Sections from this kidney (left) show only a slight degree of parenchymatous degeneration and isolated foci of round-celled infiltration.

Experiment 2.—Thirty-Minute Compression.—The round-celled infiltration is more marked than in the kidney of fifteen-minute compression. It is focal and rather unequally distributed through the kidney, some sections showing little infiltration, while others show more. There are distinct, but not very advanced signs of parenchymatous degeneration.

Experiment 3. — Forty-Five-Minute Compression. — The round-celled infiltration is much more marked than in the thirty-minute kidney. It is most evident in the cortical portion, but quite extensive throughout the kidney, diminishing toward the papillæ. The parenchymatous degeneration of the renal epithelium is also more marked than in the thirty-minute compression. The cytoplasm everywhere stains poorly. Some tubules contain hyaline and finely granular casts. There are some evidences of increase in the interstitial connective tissue. In this kidney we see, for the first time, slight traces of calcification, beginning in the most markedly degenerated tubules. These are rather indefinite.

Experiment 4.—One-Hour Compression.—(Fig. 2).—In addition to the round-celled infiltration and more marked parenchymatous degeneration, as compared with the kidneys compressed for thirty and forty-five-minutes, the most important feature of the sections of this one-hour kidney is the striking increase in the calcium deposits in those tubules which, in the kidneys of Experiments 2 and 3, compression for thirty and forty-five minutes had shown the most advanced degenerative changes. In the forty-five-minute kidney, there were only suggestions of calcium deposition, while in this one-hour kidney the calcium deposits were so evident *that they could be seen in the sections with the naked eye.* The lime salts are limited to the tubules, being deposited within and about the degenerated epithelium, leaving an open lumen.

Litten has explained this calcium deposition in the following manner: After the degenerated cells undergo necrosis, a deposition of calcium salts occurs in and about them, not because the cell is dead, but because, in the process of dying, the albumin of the cell is so altered as to possess or attain an affinity for calcium to form calcium albuminate. Litten believes that two factors are essential for the production of the calcification, first, necrosis, and, second, restoration of the circulation. This explains why, in our series, the calcium deposit is so much more marked than in cases of permanent ligation, for in such cases the circulation is not reestablished, with the exception of a little collateral circulation. Litten states that the interstitial tissue, the blood-vessels and glomeruli, always remain calcium-free, because these structures have remained unchanged. Litten showed in his experiments that it required compression for more than four hours before degeneration of the interstitial tissue, blood-vessels and glomeruli occurred.

Experiment 5.—One and One-Half-Hour Compression.—(Figs. 3 and 4.)—The deposits of calcium are much increased in number and distribution. The epithelial cells of the convoluted tubules are generally destroyed and absent. In some areas a few tubules show persistent epithelial cells, with nuclei intact. Such focal preservation is probably the result of collateral circulation. In many of the tubules the epithelial lining is completely replaced by calcium deposits. Some of the straight tubules also show these calcium deposits as long, solid cylinders. (Fig. 3.) Even at the papillæ, some calcium deposits can be detected within the tubules. (Fig. 4.)

SUMMARY

The changes in all of the sections are seen to consist, first, of round-cell interstitial infiltration; later, parenchymatous degeneration of the secreting epithelium; and, finally, necrosis of the secreting epithelium with the deposition in and about it of lime salts. The blood-vessels, although congested, show no degenerative changes, and the glomeruli are noticeable in that they show no special changes. The capillary tufts are somewhat congested, but the glomerular space is normal, as a rule, and Bowman's capsule is intact.

The round-cell infiltration, which increases progressively with the length of temporary compression of the renal vessels, shows a marked focal distribution, even when generally present, and is found most marked in the cortex between the tubules just beneath the capsule, less marked in the boundary zone of the pyramids and decreases toward the papillæ. Litten, however, in his report emphasizes the fact that he did not find any interstitial infiltration in any of his experiments.

The parenchymatous degeneration, and later necrosis of the epithelial cells of the tubules, show how dependent they are on the blood-vessels for their nourishment, and that, in the rabbit, they cannot stand even temporary interruption of this supply for more than three-quarters of an hour. One-hour compression causes marked necrosis and calcification. The parenchymatous degeneration, also, is most marked in the cortex, less in the boundary zone, and decreases toward the papillæ; and it also is characteristically seen in patches. Even when the degeneration is intense and general there are always ribbon-like areas of intact tubules whose epithelium is normal. This, as Litten pointed out, is due to some collateral circulation.

Finally, if the compression has been long enough the degenerated cells undergo necrosis and then the deposition of calcium salts occurs in and about them. In the rabbit this occurs if the compression of the vessels has been one hour or longer. In his experiments Litten found that, when the ligature was left on an hour and a half or longer, the epithelium of the convoluted tubules of the cortex and of the boundary zone is doomed to destruction and does not regenerate, even though it again receives arterial blood. Morphologically, however, he found that this necrosis did not show itself for some time. In our experiments we found that, when the kidney was removed forty-eight hours after compression of two hours, marked parenchymatous degeneration was already evident, the cytoplasm staining very poorly and faintly and the nuclei being undemonstrable to a large extent (Fig. 1). Histologically the epithelial cells are found well preserved immediately after taking off the ligature. By the use of indigo-carmin, which is excreted by the intact cells (staining them blue), but not by the destroyed cells, Litten finds that one cannot tell from the morphologic appearance of the cells whether they are functionally normal or not, or how long they have been dead, for immediate injection of indigo-carmin after removal of the ligature applied for two hours shows bluish coloration of the nuclei of the epithelium of the convoluted tubules absent, or present only here or there; that is, there is permanent loss of function, with at first morphologically intact cells, which later become necrotic. Litten further finds that the deposit of calcium is already evident twenty-four hours after compression, and increases in proportion to the progress of the cell death, and progresses so rapidly that several days after the compression large coherent masses are evident.

By injection of the blood-vessels Litten found that they could stand cutting off of the circulation for even four hours without causing serious change in them, and that they were permeable forty-eight hours and even many days after the original operation. Longer compression causes complete necrosis of all of the epithelium of the kidney, even of the areas that were supplied by collateral arterioles.

CONCLUSIONS

From the above series of experiments in the rabbit the following conclusions may be drawn:

1. Temporary compression of the renal vessels, if continued thirty minutes or less, causes very slight changes in the kidney.

2. Temporary compression of the renal vessels, if continued forty-five minutes, causes considerable parenchymatous degeneration and interstitial infiltration.

3. Temporary compression of the renal vessels, if continued one hour, an hour and a half or two hours, causes marked permanent degenerative changes in parenchyma, as is evidenced by marked interstitial infiltration and extensive coagulation necrosis of the tubular epithelium; and, later, by the deposition of calcium in and about the destroyed tubular epithelium.

Note.—As the rabbit's kidney is much more susceptible to interference than the human kidney, it is probable that the human kidney would stand temporary compression of its vessels for a longer time than the rabbit's kidney, before these permanent changes would be produced in its parenchyma.

103 State Street.

ABSTRACT OF DISCUSSION

Dr. Victor D. Lespinasse, Chicago: As a necessary step in my work on anastomosis of the renal artery, I have been compelled to shut off the blood-supply to the kidney by clamps. In my first series of experiments in which the kidney was removed and then the artery to the opposite kidney clamped, cut and anastomosed, all the dogs but one died. In this dog the blood was shut off from his sole kidney for approximately one hour. In those that died the cause of death was shock, death occurring within twenty-four hours after the operation. The bladders were empty, although there was no obstruction to the blood-flow in the anastomosed renal artery. In the second series I clamped, cut and anastomosed, in one renal artery, the clamp remaining on approximately fifty minutes. Ten days later the other kidney was removed. In this experiment all the dogs lived. Hence a dog's kidney will withstand for one hour complete anemia and still be able to sustain life.

Dr. D. N. Eisendrath, Chicago: Dr. Strauss and I became interested in this work chiefly from its surgical importance. Last winter, at a meeting of the medical society in Chicago, we had a discussion as to the advisability of using this method of clamping the renal arteries and veins during operations for the removal of stone in the kidney, and as to what the effect of such temporary anemia on the structure of the organ would be. It was thought that this might do more harm than the losing of a little blood during the operation, leaving the temporary anemia out of the question. Dr. Betton of Chicago said that it might be of interest to study the effects of such temporary anemias as we repeatedly get in surgical operations on the kidney, and Dr. Strauss and I undertook this investigation last winter. Of course, there is this much to be said in regard to the comparison of rabbits' and human kidneys: the rabbit's kidney is an extremely sensitive organ to the withdrawal of blood. So one can deduce only that whereas the slides, shown here, of ligations of fifteen, thirty and forty-five minutes, exhibit practically no changes in such a sensitive organ as the kidney of the rabbit, probably such changes would be still less likely to occur in the less sensitive kidney of the human being when ligated for the same length of time. It is not until the clamp has been left on for an hour that one sees definite changes, such as an extensive amount of round-cell infiltration, degeneration, calcium deposition, etc. The interest of this to the surgeon is that we can safely, judging from the fact that the rabbit's kidney does not show marked changes from a ligation of less than an hour, compress the renal vessels of the human being for half an hour and cut off the blood-supply. No surgical operation on the kidney would be likely to require compression for a longer time than this. For that reason, we feel that this work will be of considerable help to the general operating surgeon.

DR. YANDELL HENDERSON, New Haven, Conn.: The work of Carrel at the Rockefeller Institute has shown a great difference between the effects of interference with the circulation on the side of the vein and on the side of the artery. It seems to me that in such experiments as those of Drs. Eisendrath and Strauss, care should be taken to note whether both artery and vein were shut off, or whether partial compression was used, shutting off the vein entirely and the artery partially. If the vein were compressed completely and the artery only incompletely, the outflow would be shut off and the renal blood-vessels (both arteries and veins) would be distended by the full arterial pressure. The work of Carrel shows that many organs stand interference with their arterial supply fairly well, but are greatly harmed by interference with their venous drainage.

DR. H. GIDEON WELLS, Chicago: Calcification of the tubules is usually very extensive in experiments with the kidneys of rabbits, and one has to consider the fact that the blood of these animals contains more calcium than does that of either the carnivora or the omnivora. The results of such experiments have been applied to the problems of general calcification. This, I believe, is entirely and fundamentally erroneous, for the reason that in the case of the calcification of the necrosed tubules of the rabbit's kidney there is the same process as in calcification of dead organic material in the urine, in which there is a solution of certain organic and inorganic salts, differing from calcification occurring within the body, when the calcium comes from the circulating blood.

A point brought out with regard to Litten's work is that he found no definite relation between the functional changes in these cells and the anatomic alterations. We are too little inclined to bear in mind the entire discrepancy between functional and histologic changes. Although this lack of correspondence of structure and function has been frequently mentioned, yet one so frequently sees it disregarded that I do not hesitate to emphasize this point. The opposite condition also holds good, namely, that extreme anatomic alterations are not necessarily productive of defective functional capacity. In Washington, in May, I presented before the American Association of Pathologists and Bacteriologists a paper describing the effects of the most extensive possible fatty degeneration that I had been able to produce in the liver. I found that the liver-cells in these cases showed as great a power to destroy uric acid, which is difficult to oxidize, as do the cells in the normal liver. Therefore, cells may show extensive histologic changes and yet be functionally competent; and may also show no histologic changes and be totally incompetent.

DR. DAVID C. STRAUSS, Chicago: In the beginning of the paper I did not care to refer to the literature, because there is so much of it, and most of it does not apply to temporary compression, but to permanent ligation. In regard to the functional effect of temporary compression of the renal vessels, I found mention of some experimental work done by Ludwig on dogs. He found that temporary compression of the renal pedicle often caused temporary anuria and albuminuria that remained for hours, or even days; but this did not always follow. In our paper we simply wanted to refer to the anatomic changes produced. As Dr. Wells has pointed out, the functional changes ought also to be studied; however, this is simply a preliminary study. With reference to whether in our experiments there was complete compression of the vein but not of the artery, I would say that the clamp used by us was very strong and was protected by rubber, so that there was little chance of failure to compress the artery entirely. Moreover, in every case I felt the artery in order to be sure that there was no pulsation between the clamp and the kidney, and in some cases put on a second clamp to be more certain. In regard to Dr. Wells' remarks concerning calcification, I did not quite understand the point he made about the deposition of calcium being the same as in the urinary bladder.

DR. H. GIDEON WELLS, Chicago: There is simply a precipitation of calcium as from a sponge. It is not comparable to the calcification of the bronchial glands, for instance.

DR. DAVID C. STRAUSS, Chicago: Litten, in his article, points out that the chief reason why there is so much more calcification in these temporary compression experiments than in experiments in which permanent ligation is done, is the fact that the blood-vessels are not destroyed by the brief temporary compression, and that the circulation through the renal vessels is reestablished. This allows further deposition of calcium to occur; whereas, when the vessels are ligated permanently, the only source of calcium deposit is from the collateral circulation. We did not observe functional changes. They ought, however, to be observed.

THE ETIOLOGY OF EPITHELIOMA *

ARTHUR E. HERTZLER, M.D.

ROSEDALE, KAN.

I. THE DEVELOPMENT OF FIBROUS TISSUE

The result of some studies in the development of fibrous tissue as observed in wound-healing form a necessary introduction to the consideration of the behavior of connective tissue in its relation to developing epithelium. It will be necessary, therefore, to present in outline some researches already published.[1]

The first change in the healing of any wound is the exudation of a colorless serum. Within a few minutes this material begins to coagulate, forming bands extending from one wound surface to another. These bands become fully formed after a few hours. They take the direction most effectual for union. I speak of this process as coagulation because the fibers so formed stain by Weigert's fibrin stain and stain red by Mallory's stain, as is characteristic for fibrin (and Mallory's fibroglia fibrils), and because those things which prevent the coagulation of blood prevent the formation of these fibrils. We have then a tinctorial and a physiologic test in agreement that the process here observed is identical with that of blood coagulation. These fibrils after a few days lose their affinity for the Weigert and the red in Mallory's stain and stain blue with the latter and are, therefore, fibrous tissue. It remains to determine that the fibers staining blue with Mallory's stain after three to six days are the same as those which stain red with Mallory's and blue with Weigert's stain during the first few days.

Two facts are available for this proof. In a large series of experiments in which corn-pith was stitched to a peritoneal surface the fibrin bundles formed over the surface geometrically ("in a mathematical manner" —Kulmann). These results are constant.

After the change in tinctorial reaction has occurred, the fibers have an identical arrangement. If, therefore, the fibrin fibers are replaced by fibrous tissue the arrangement is identical. That they are not replaced finds its chief argument, however, in that a part of a single fiber may stain blue while the remainder still takes the red stain. These results also are constant. From these facts I conclude that the initial process in wound healing is the formation of fibrin identical with that formed in the coagulation of blood, and that the fibrin fibrils are converted into fibrous tissue fibrils.

II. CHANGES IN CONNECTIVE TISSUE IN ARTIFICIALLY INDUCED EPITHELIAL CELL PROLIFERATION

When Sudan III in olive oil is injected beneath the epithelium, epithelial cell proliferation takes place to such an extent as to simulate very closely a beginning epithelioma. The influence of the Sudan oil, according to Fischer, is to act as an attraxin. No attention has been paid to the fact that the connective tissue in the region of the developing epithelium loses its specific tinctorial reaction to connective tissue stains and that epithelium does not proliferate in regions where this change in the connective tissue has not taken place. From study of sections of specimens obtained soon after the oil has been injected and for short intervals afterward, it seems that the connective tissue changes precede the epithelial proliferation. The epithelial proliferation, too, takes place after the use of those dyes only which induce these changes in the connective tissue, namely those of the OH group. The changes in the connective tissue are the reverse of those changes which take place when fibrin changes to fibers, that is to say, the changes are from blue to red instead of red to blue. I am not certain that I have succeeded in completing the reverse process. Fibers occur which stain red by Mallory's stain, but I have not succeeded in reversing the process far enough to get a positive reaction with Weigert's fibrin stain. As a corollary to this line of evidence it may be mentioned that epithelium does not develop in wound-healing in the presence of adult connective tissue. The use of Sudan in the treatment of chronic ulcers has been supposed to act by stimulating the epithelium to proliferation. The connective tissue changes produced by the Sudan when used as an ointment are identical with those induced when the dye is injected. I conclude from such studies that the changes in the connective tissue are probably the essential factor in the production of the epithelial proliferation. When the healing of chronic ulcers is attempted by surgical means we empirically bring about the same condition which we produce by the Sudan, that is, fibrin is supplied, or in other words, we cause the chemical reaction of fibrous tissue to approach that of fibrin.

III. THE CONNECTIVE TISSUE CHANGES IN EPITHELIOMA

In advance of epithelial proliferation in beginning cancer the connective tissue undergoes changes similar to those artificially produced in the Sudan experiments. It no longer stains in a characteristic manner by Van Giesen and stains a paler blue by Mallory's stain. The reaction to Van Giesen is identical with that given by the connective tissue in the Sudan experiments. The results are so constant as to be most valuable in the determination of the clinical character of epithelial cell proliferations. The chief matter of interest, however, is the occurrence about certain cell-nests of small bundles of fibrils which correspond to my fibrin fibrils and to Mallory's fibroglia fibrils. These are found in small numbers in a great variety of tumors. Whether these fibrils result from a reverse change from blue to red or whether they are newly formed is difficult to determine, I am disposed to regard the latter as probable; in the first place, because this corresponds to Mallory's opinion, and in the second place, because one cannot distinguish the change from a degeneration process. In certain rapidly growing tumors granular material reacting to Weigert's stain is found which corresponds to the granular fibrin of the physiologists, which, as stated in my previous paper, does not develop into fibrous tissue. This explains the paucity of stroma in certain rapidly growing tumors.

In exact harmony with these changes in epithelioma and in the Sudan experiments are the changes observed in x-ray dermatitis and beginning epitheliomas resulting from the exposure to the x-rays. These lesions seem to supply the missing link between the Sudan experiments and spontaneous epithelioma. In the x-ray lesions, investigators are in agreement that the changes are primarily in the connective tissue. We have in each of these conditions, the Sudan experiments, the ray proliferations and spontaneous cancer, cell proliferation and changes in the connective tissue and an attempt to determine which is primary is not an easy matter. In the ray tumor and particularly in the Sudan experiments the changes in the connective tissue precede epithelial cell proliferation and there is much collateral evidence that the same is true in cancer.

In the summary of such collateral evidence we are reminded that it was the theory of Thiersch that the primary factors lay in the connective tissue. The fact that blood-vessels are not formed in granulation tissue after the fibrin stage has passed has seemed to me to be in accord with the observation already made that epithelial cells do not develop in the presence of normal connective tissue. These changes in the connective tissue are attended by round-cell and leukocytic infiltration. That cancer is most apt to develop at sites where chronic irritation is most apt to occur is perhaps the most constant factor in cancer etiology. The evidence of inflammatory reaction is present before the epithelial proliferation and the change in the connective tissue occur; in the presence of such irritation it seems but logical to assume as a working hypothesis that the changes in the connective tissue stand in a causal relationship. The x-ray cancer and the epithelial cell proliferation produced by Sudan can be pretty definitely demonstrated as being constantly preceded by connective tissue changes. If the hypothesis that the primary change occurs in the connective tissue be accepted, the nature of that primary change is yet to be determined. In these studies several points have appeared which are of interest. The fibrin fibrils occur about cancer nests, but their causal relation to the developing epithelial cell cannot be determined. The fact that the leukocytes are present in these processes preceding cancer development may in some remote way have to do with the process of fibrin formation. It would seem, however, that this is expressive of reaction against the invading epithelium, just as fibrin, then fibrous tissue forms in granulomas and not as a causal factor. Returning to the experiments with Sudan, we are reminded that those dyes only which have the power of combining with lipoids *in vivo* have this power and that they are all dyes belonging to the OH group. The negation of the properties of the lipoids may permit the processes of coagulation—that is, fibrin formation—to become active.

We know also that cancer cells have a predilection for metastatic formation in certain situations. These sites of predilection correspond in a rough way with the class of phenomena above considered.

These facts have a constant harmony which makes a specific significance probable. In a previous paper[2] I attempted to follow out on clinical grounds some of the circumstances under which cancers develop. In most situations irritations plus an alkaline secretion are coexistent. This crude hypothesis may have some value as a working basis though a comprehensive statement cannot be entered into at this time. We may assume perhaps that a chemical balance has been broken. The latter would seem to be necessary in the explanation of the formation of metastasis, while the former might obtain as a preliminary factor in the development. I will remind you that epithelial metastases occur most frequently in those regions where leukocytes are most abundant (the lymph-glands) or where this prefibrin substance is most abundant (in subendothelial tissues). Metastasis, according to this hypothesis, becomes very closely related to the relation of leukocytes to blood coagulation. The relation of the leukocytes to chronic inflammations and the etiology of epithelioma halts at the same point. We must look to the physiologist for more light.

[2] Hertzler, A. E.: The Etiology of Epithelioma; A Laboratory and Clinical Study, THE JOURNAL A. M. A., Feb. 8, 1908, p. 425.

The relation of the fibrin fibers, of which I speak, to the fibroglia fibrils of Professor Mallory requires a word. They react to the same dyes and are found in the same *situations, but I am at a loss to know how to go about* establishing proof of their identity. Identity cannot be proved by fibrils produced otherwise than in wound-healing where the age of the fibrils can be accurately determined.

Studies in fibrils less than forty-eight hours old have convinced me of their identity. I desire to say a word about their relation to the cells which he believes produces them. I cannot agree that they may be produced by the cell, for the simple reason that they develop before the advent of the cells and in situations inaccessible to cells. They bridge areas not possible for cells to traverse [illegible] according to mathematical laws [illegible] sumption that they are precipitated out of an amorphous exudate, while the arrangement cannot be explained by the assumption that they are the product as such of the cells; furthermore, at no time can any organic connection between the fibrils and the cell be demonstrated. What influence the cell may have in changing them from fibrin to fiber or what part the cell may have in the production of the material forming the amorphous exudate out of which the fibrils are precipitated by the action of some other factor, I cannot enter into here.

SUMMARY

1. The formation of fibrin is the first step in the formation of connective tissue.
2. Epithelium develops in the presence of fibrin only.
3. In the artificial production of epithelium by Sudan III the first changes are in the subepithelial connective tissue.
4. In x-ray cancer the epithelial development is preceded by changes in the connective tissue which are tinctorially identical with those which take place in the Sudan experiments.
5. The changes in the connective tissue in beginning epithelioma are tinctorially identical with those in the Sudan experiments and in x-ray cancer.
6. The factor most constant in cancer etiology is chronic irritation. Chronic irritation produces the changes above enumerated.
7. The sequence of phenomena above enumerated suggests as a working hypothesis that the etiology of cancer is associated with the lessened acidophilic properties of the connective tissue whereby it approaches fibrin in tinctorial reaction.

A FURTHER CONSIDERATION OF THE QUESTION OF PERMANENT DRAINAGE IN CERTAIN CASES OF PANCREATITIS *

LE GRAND GUERRY, M.D.
COLUMBIA, S. C.

At the Virginia Hot Springs meeting of the Southern Surgical Association, I read a paper entitled "A Plea for the More General Use of Cholecystenterostomy in Certain Cases of Pancreatitis." I said in part that I believed that the operation advocated was thoroughly consistent with the nature of the diseased process, namely, a chronic inflammation of the pancreas, whether the etiologic factor were gall-stones or infection independent of and apart from stone formation.

From what I have been able to read in books and the current literature, and have observed in the actual work of many large clinics, the operation of cholecystenterostomy in its *relation* to chronic or *interstitial pancreatitis* is not as generally in use by surgeons in this country as it should be.

The whole proposition hinges on this point: It appears that quite a number of cases of chronic pancreatitis require more or less permanent drainage to effect a symptomatic and physiologic cure; that if the pancreatic inflammation has progressed to a certain stage the operation of cholecystotomy does not afford drainage for a sufficient length of time to allow the trouble to subside; indeed, there is a point reached when the pancreatitis itself is incurable, although the symptoms due to insufficient bile drainage may be relieved by operation. In other words, if the pancreatitis which started as interstitial lasts long enough, the islands of Langerhans become involved and we then have the so-called interacinous pancreatitis with its resultant diabetes.

When we consider the comparatively small size of the bile channels, the very low blood-pressure under which bile is secreted, the slight force behind to force it on to the intestinal tract, it is easy to understand that in those cases in which the common duct passes through the head of the pancreas a comparatively slight obstruction would be sufficient to cause the damming back and absorption of the bile. I shall briefly relate a case which is typical of quite a number to serve as a concrete illustration.

M., a man aged 38, married, several years ago had an attack of pain in the gall-bladder region with very slight jaundice, pain occasionally radiating under right shoulder, slight fever, indigestion, etc.; these attacks would occur at frequent intervals; there was a gradual weakening and loss of flesh; no sugar in the urine. The diagnosis was gall-stones or pancreatitis (chronic) or both. At the operation a slightly distended gall-bladder with no stones was found; the bladder was full of the characteristic ropy, tarry, black bile with well-marked colon-bacilli odor to it. The pancreatic head was markedly enlarged. Operation consisted in cholecystotomy after the common duct had been thoroughly explored and a probe passed into the duodenum to insure the patency of choledochus; drainage was continued for three months, and during this time the patient not only gained 20 pounds in weight, but was completely restored to health. This is a sentence from a letter received three months after the wound had been closed: "Dear Doctor: I have just had another attack very much worse than any before my operation; what shall I do?" On my advice, the patient returned to the hospital, at which time cholecystenterostomy was done, with the result that he has been permanently relieved from all his symptoms and is now in perfect health.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

I think it most important to try to determine at the primary operation which cases need permanent drainage and which do not, and not to wait for a recurrence of symptoms to point us to the error of our way, for it is my opinion that this malady is not only a more frequent one, but much more important than is the general belief.

The following from Mayo Robson[1] is very much to the point:

> A simple drainage of the gall-bladder by cholecystotomy is frequently unsatisfactory and cannot be relied on in well-marked cases of obstruction, as drainage of the bile passages is not sufficiently long-continued. This applies especially to the cases in which the interstitial pancreatitis has persisted for some length of time, in which cases, although a cholecystotomy may lead to a disappearance of the jaundice and the digestive symptoms may be alleviated, the metabolic signs found in the urine many months, or even years subsequently, show that recovery has only been partial.

To my mind it is most important to draw a distinction between chronic pancreatitis due to gall-stones and chronic pancreatitis due to infection independent of and apart from the presence of stones; in the first case simple removal of the stones and temporary drainage of the gall-bladder gives permanent relief, because we remove the cause of the disease: in the other case, however, the trouble lies outside of and independent of stone formation, and these cases, within the bounds of my experience, at least, are much more likely to require permanent drainage to affect a cure. On this point Mayo[2] says:

> I am impressed with the fact that chronic pancreatitis is not only a more frequent malady than has been supposed, but a more important one. In looking back over considerable experience in surgery of the gall-bladder and bile-tract, I find that a number of cases that have failed to make a good recovery, failed because of pancreatic complications. It is certain that a much larger proportion of cases, especially those with a distended gall-bladder and dilated common duct, with or without stones, should be treated by a cholecystenterostomy, than has been the practice among surgeons.

This position has been forced on me by an experience which I believe is rather unusual. Very briefly it is as follows: I have had in all fifteen cases of chronic pancreatitis; out of these cases the first twelve patients were treated by cholecystotomy, with the result that nine out of the twelve returned for a second operation, made necessary by a recurrence of the symptoms, at which time cholecystenterostomy was done. I have heard recently from eight out of these nine patients and they all report their general health and strength as being in every way satisfactory. Of the nine patients reoperated on in only one was the pancreatitis associated with gall-stone disease. In the last three cases I have felt justified in making permanent drainage at the primary operation, with the result that the trouble was ended at once. In a recent article Ochsner says, "In rare cases in which the common duct is permanently obstructed, cholecystenterostomy may be indicated." In fully half of my secondary operations for this trouble the patency of the common duct has been proved by passing a probe through the duct into the duodenum, and yet recurrence has taken place.

My experience is, I believe, unusual; the number of cases in which there has been recurrence is out of the ordinary and will probably never be paralleled. I would not for a moment encourage the inference that I believe that two-thirds or one-half of the patients treated by simple drainage would have to be operated on again, but I do insist that this experience is so striking as to merit serious attention; and, incidentally, it suggests that the future will have to determine between temporary or permanent drainage for certain cases of infection of the gall-bladder and biliary passages. There has been one death in this series of cases from ether pneumonia.

I feel, then, that this conclusion is justified: When operating for chronic pancreatitis, if the conditions present do not necessitate cholecystenterostomy, they do present the strongest possible reasons for not making permanent drainage.

PATHOLOGY OF GALL-BLADDER AND BILE-TRACTS*

J. P. RUNYAN, M.D.
LITTLE ROCK, ARK.

In the study of the pathologic physiology of the gall-bladder and gall-tracts we are constantly confronted by the facts that all the various digestive organs, the liver, duodenum, pancreas, stomach, etc., are functionally synergistic, and not, as was formerly supposed, separate and incoordinate units, and that disease in one portion may manifest itself primarily by symptoms referred to an entirely different part. There are also universal symptoms, symptoms common to disease of any part of the digestive tract, which are still considered as neuroses due in some mysterious way to anything or to nothing in particular. The symptomatology of the diseases of the digestive tract is very confusing; and we need not wonder therefore why nearly all diseases of the gall-bladder and bile-tracts are not recognized early and are permitted to develop into dangerous and serious complications before operation is undertaken. Since the pancreas has the fatal defect of sharing terminal facilities with the common bile-duct, and since to that unfortunate arrangement the majority of the diseases of the pancreas are due, for this exposes it to infections and diseases of the gall-bladder and ducts, the early recognition and removal of the pathologic conditions in the gall-bladder and bile ducts is of paramount importance. It is the object of this paper to review the pathology of these conditions and their bearing on an early diagnosis.

Gall-stones are by far the most important pathologic factors we have to deal with. The most important factors which contribute to their formation are stagnation and infection. In old age the muscular tissue about the bile passages atrophies, and this interferes with normal movements of the bile. Lacing and pregnancy in women, and abdominal tumors and adhesions have a tendency to distort the bile passages; these conditions also produce stagnation by pressure. Heredity also plays a part in predisposing to the formation of gall-stones. Stasis is the great factor favoring the development of an infection of the biliary passages. Bile is usually sterile in spite of the open communication that exists between the common duct and the intestinal tract. The current of flow carries material into the intestines, and, even though bacteria are artificially introduced into the bile, they may be carried away by the current without doing any harm. On the other hand a mere ligation of one of the larger bile-ducts in an animal often suffices to set up an inflammation.

---

[1] Robson and Cammidge: The Pancreas, Its Surgery and Pathology, p. 446.

[2] Mayo, W. J.: Surg., Gynec. and Obst., December, 1908, p. 611.

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

The following facts have been cited in support of the view that infections of the biliary tracts enter by way of the portal vein more frequently than by the common duct. Adami and Ford have asserted that there is a constant passage of bacteria through the mucosa of the healthy intestines; bacteria introduced into the blood may be excreted in the bile (Cushing). The bacteria causing cholecystitis are often not those found commonly in the duodenum. The infection of the biliary passages above a ligature around the common duct could hardly come from an ascending infection. Finally if an enteritis be caused by the administration of arsenic, etc., and if the animal is fed some easily recognizable organisms, such as *Bacillus prodigiosus,* the organisms can often be demonstrated in the bile passages. These facts render it very probable that infection frequently takes place by route of the portal vein. The bile is apt to contain bacteria in pneumonia, typhoid fever and other infections. The bacterial infection produces an inflammation of the mucous membrane and a desquamation of its epithelial cells. These latter contain undissolved cholesterin. They likewise contain calcium salts and these probably react to form the insoluble calcium salt of bilirubin. From this salt, as well as from the amorphous cholesterin in the cells, the biliary calculus takes its origin. Its further growth is carried on by the deposition and recrystallization of new material, especially of cholesterin. Pancreatitis about the common duct also may favor the formation of gall-stones.

In the diagnosis of gall-stones and cholecystitis the history is of great importance and little attention should be paid to the erroneous statement that gall-stones produce no symptoms until impaction takes place. We must also disregard the age of the patient or at least remember that gall-stones can occur before middle age. In fact we should look on every patient who presents himself with indigestion as having some serious lesion of the stomach or gall-bladder, perhaps with complications—till the seriousness is disproved.

The most prominent symptoms of gall-stone disease are a history of long-standing dyspepsia, a capricious appetite, constipation, marked flatulence, independent for the most part of the taking of food, associated with discomfort when the stomach is empty and with comparative ease at night after eating a little. In gall-stone disease we have often at the beginning a sense of constriction but not of actual pain and this sense of constriction is accompanied by a sensation of chilliness which is characteristic. Jaundice, hematemesis, etc., are all late symptoms which will clear up the diagnosis but so late that complications are always present.

From the surgical standpoint it does not make any difference whether we have gall-stones, gastric or duodenal ulcers, pericholecystic or perigastric adhesions; the same incision will relieve them all.

Inflammation of the gall-bladder and bile tracts may depend on causes originating within the ducts, as formation and retention of gall-stones or micro-organisms brought to them from the circulating blood, from the bile or ascending from the intestines. Disease of the pancreas also may cause inflammation in these parts by obstruction of the common duct. Even the majority of tumors of the gall-bladder, the carcinomas, are frequently the result of the trauma and continuous irritation resulting from gall-stone disease.

The disturbances produced by diseases of the gall-bladder and bile-ducts may be conveniently grouped under the following headings:

1. The resulting jaundice.
2. The result of the occlusion of bile from the intestines.
3. The accompanying pancreatitis.
4. The effect of occlusion of the pancreatic secretion from the intestines.

THE RESULTING JAUNDICE

Whenever the lumen of the common duct or both hepatic ducts are obstructed from any cause and the liver cells continue to secrete bile, then the gall-bladder and bile passages become filled with the secretion, the bile pressure within them increases, the liver cells are separated and the bile is absorbed in the lymphatic system or directly into the blood. Thence it is distributed and deposited in various tissues. The bile salts are the most toxic of the constituents of the bile that pass into the blood and are responsible for some of the resulting toxemia. The presence of bile also interferes with the coagulating power of the blood, and prevents operation in some cases on account of the tendency to hemorrhage by diapedesis.

THE EXCLUSION OF BILE FROM THE INTESTINES

The exclusion of bile from the intestines interferes seriously with the absorption of fats, only about 40 per cent. of the fats taken in the food being absorbed, as to the normal 90 per cent. In cases in which the bile is occluded from the intestinal tract we must pay close attention to the diet so as to maintain the nutrition of the patient. The diet should consist principally of proteids and of higher carbohydrates. Fat should not be given, for if present, it will undergo excessive cleavage through the action of intestinal bacteria and pancreatic ferments. The products of the decomposition are very irritating and are responsible for the diarrheas and other disturbances present. What influence the absence of bile exercises on the bacterial decompositions of the lower intestinal tract we are not surely informed about. We know, however, that the putrefaction of proteid material is increased.

THE ACCOMPANYING PANCREATITIS

According to studies made by Dr. C. H. Hoffman, pathologist of the College of Physicians and Surgeons of Little Rock, Ark., the most frequent causes of acute and chronic pancreatitis are gall-bladder and duct diseases. Mayo in 325 operations on the common and hepatic ducts found the pancreas involved in 22 of the cases. Quénu and Duval estimate the simultaneous occurrence of gall-stone disease with chronic pancreatitis as being close to 50 per cent. Williams and Bush in a collection of 83 cases chronicle their presence in nearly 40 per cent. Egdahl analyzed 105 cases and concluded that 42 per cent. of the cases of acute pancreatitis were associated with gall-stones, and inclines to the opinion that they are the most common causes of pancreatitis.

Opie established the proof of this relationship in a post-mortem in a case of Osler's operation by Bloodgood, in which a small stone occluded the ampulla of Vater, forming thereby a continuous passage for the bile from the common duct into that of the pancreas. This he supplemented later by the addition of seven other cases and inferred that in many cases the stone may be lodged temporarily, but long enough to damage the pancreas, and then may escape, without leaving any further evidences of its impaction. Half of the cases examined by Opie showed more or less contraction or obliteration of the duct of Santorini so that it could not perform the functions of Wirsung's duct, when that duct was obstructed by the ordinary passage of an average-sized gall-stone through the pancreatic portion of the common duct without impaction at the ampulla. From this we understand that the actual lodgment and retrojection of bile frequently takes place.

Pancreatitis can be produced also by regurgitation of the contents of the duodenum into the diverticulum of Vater, the route having been opened by the passage of a gall-stone. The head of the pancreas encircles the common duct in nearly two-thirds of all cases. Stones lodged in that portion of the duct press on the pancreas and produce partial if not complete obstruction of its secretion, which can be readily infected either from the duodenum through Santorini's duct or through the ampulla of Vater. The bile is nearly always infected in all cases of common-duct stone and we must consequently anticipate more or less virulent infections of the pancreatic secretion from the same cause.

Flexner injected bile mixed with mucus into the pancreatic duct and found that this diluted bile produced only a mild pancreatitis while if the bile was injected undiluted an acute phlegmonous inflammation resulted. This will be sufficient to show that the etiology of pancreatitis is in most cases identical with that of cholecystitis and cholangeitis.

THE EFFECT OF EXCLUSION OF PANCREATIC SECRETION FROM THE INTESTINES

Complete exclusion of pancreatic juice from intestines without concomitant exclusion of bile is extremely rare. A closure of both ducts does not occur frequently, and likewise a total degeneration of the secreting glandular parenchyma is rare.

Muller studied the feces of several patients who had extensive pancreatic degeneration, and found the absorption of carbohydrates not at all affected by the disease. He found that the absorption of the proteids was only slightly affected, and that the total quantity of fats absorbed was likewise not far from normal. The cleavage of fats in the intestines, however, was considerably diminished, for of the fat in the feces only 40 per cent. was found split into soaps as against the normal of 84 per cent. Others claim that the absorption of fats is greatly diminished. Weintraub's patient lost 25 per cent. of the fat taken in the food and Doucher's two patients lost respectively 52 and 83 per cent. of the fat taken in the food. Later observers, particularly Croftan, have established that in pancreatic obstruction the stools are bulky, because a great deal of the pabulum fails to be assimilated at all and therefore escapes absorption. There is much fat in the stools and the muscle nuclei pass through the intestine in an undigested form (Schmidt's test); in addition lipase may appear in the urine (Hewlett's test); also pentose (Cammidge's reaction) and much dextrose. Dr. Hoffman informs me that he has found the Cammidge reaction of a great deal of service in the diagnosis of chronic pancreatitis but of no value in the acute form.

TREATMENT

The nature and extent of the operation for gall-bladder and gall-stone disease must depend on the condition of the pancreas.

In gall-stone disease with chronic pancreatitis the removal of the stones with temporary free drainage by means of a cholecystostomy is generally sufficient. This drainage relieves the infection caused by the stones and also will do away with the pressure which the pancreas exerts on the common duct. Whenever we have reason to believe that the pancreas is involved, unless there is malignant disease of the gall-bladder or the function of the organ has been destroyed by obliteration of its cystic duct, the removal of the gall-bladder is not advisable. A previous history of cholangeitis, frequent attacks of jaundice, or calculi in the common duct, all contraindicate cholecystectomy, for keeping the gall-bladder intact will permit a secondary cholecystenterostomy if necessary. It must be constantly borne in mind that the mucus secreted by the gall-bladder has a function and protects the pancreas.

I have long ago been impressed with the importance of chronic pancreatitis and have always advocated that all cases of distended gall-bladder and a dilated common duct with or without stones should be treated by a cholecystenterostomy. The gall-bladder has two important functions, one to secrete protective mucus, and the second to relieve the tension in the common duct at the head of the pancreas. In doing a cholecystenterostomy we should constantly bear in mind the function of the bile in the intestines and should never make our anastomosis between the gall-bladder and the colon unless circumstances demand it. The most logical place for such union is between the gall-bladder and the duodenum as near the opening of the common duct as possible, but in some cases the duodenum is placed so deep or is so firmly fixed by adhesions as to render a union there almost impossible.

In gall-stones and gall-bladder trouble complicated by an acute pancreatitis the pancreas should be incised, free drainage established and it is better to employ the anterior abdominal incision than the posterior one. If the patient's condition will permit it, and there are stones in the gall-bladder or the ducts, or an acute infection of the bile passages, the stones should be removed and drainage of bile established through a right lateral incision. If jaundice is present drainage is imperative.

It will be seen from the foregoing that in all diseases of the gall-bladder and ducts an early diagnosis is the only means we have of preventing serious complications. To wait for repeated attacks of biliary colic, for vomiting, or hematemesis, or pancreatitis to make our diagnosis before operating would be a very dangerous procedure. Since we do not wait for a mastoid abscess to produce a sinus thrombosis, or for a gastric or duodenal ulcer or an inflamed appendix to perforate and produce peritonitis why should we wait for gall-stones to impact and develop a whole train of sequelæ before operating?

1902 Schiller Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. GUERRY AND RUNYAN

DR. L. F. SCHMAUSS, Alexandria, Ind.: It is stated in the literature that gall-stones do not produce symptoms in about 90 per cent. of the cases. In 90 per cent. perhaps gall-stones do not produce symptoms early—that is, typical symptoms, like colic, jaundice, and so forth—but to say that in 90 per cent. of all cases of gall-stones there are no symptoms is wrong, and not according to the observation of anyone who gives the subject serious thought. I maintain that in all cases of cholelithiasis there are symptoms before the patient reaches old age; that in 90 per cent. of them there are more or less serious symptoms before that period, and that in at least 10 per cent of all cases of cholelithiasis the symptoms will be so severe as to necessitate operation These patients all have so called dyspeptic and neuralgic symptoms for many years, which means that we should give them more attention Not only are they diagnosed as gastralgia or neuralgia of the stomach, but even as appendicitis malaria, and so forth and this statement that 90 per cent of cholelithiasis cases give no symptoms is to a great extent responsible, I think, for these wrong diagnoses

A CASE OF DIAPHRAGMATIC HERNIA

A BAMBERGER, B S, M D
CHICAGO

I report this case not only because of the rarity of diaphragmatic hernia, but also because of the abstruse and puzzling symptoms it presented

Past History—The patient, W W, a negro butler, aged 23 had had the diseases of childhood, gonorrhea several times but denied syphilis He used alcohol and tobacco in moderation but denied coming in contact with lead in any form He had never had a similar illness and was well up to the onset of the present trouble Ten years previously he had been stabbed in the left seventh intercostal space just lateral to the anterior axillary line The cut was about 2 inches long, through which a mass looking like fat (as he described it) protruded The wound was sutured under general anesthesia and an uneventful recovery followed

Present Trouble—About 12 30 a m, July 24, 1910, he entered my service at the Cook County Hospital He gave the following history Five days previously a sharp pain started on the left side of the abdomen about 2½ inches below the costal arch, which grew so severe that he was unable to sleep that night He vomited, but had no chills or fever Bowels had been constipated since the onset of the pain, and resisted all cathartics and flushings that a physician had administered The pain on the left side of the abdomen, which had radiated to the epigastrium, and the vomiting and constipation persisted until entrance to the hospital On the day before admittance to the hospital he vomited a brownish material which as he expressed it looked like manure

Examination—The patient walked into the ward, but apparently had some pain He was well nourished There was no cyanosis or dyspnea, temperature 99 2 F per mouth, pulse, 64, respirations 24 on admittance The pupils were equal and reacted to light and accommodation There was no rigidity of the neck and no lead line along the gums The throat was negative The lungs expanded equally on both sides Dulness began posteriorly one hand's breadth below the angle of the scapula There were no abnormal palpatory, percussion or auscultatory findings The pulse was full, slow and regular The heart was on the left side of the chest, not enlarged and showed no murmurs The abdomen was not distended, and peristaltic waves could not be seen or auscultated There was tympany all over Some tenderness and rigidity were present over the entire abdomen but especially in the region of the appendix In the right anterior lumbar region there was an ovoid tumor mass tympanitic and tender, but not movable Liver and spleen were not palpable The genitalia were negative There was no stricture, prolapse or tumor of the rectum Knee jerks were present, no Babinski or ankle clonus The urine was amber, clear, specific gravity 1,038, no albumin, no sugar, no casts, leukocytes, 6 250

Course—Repeated colonic flushings and '1 2 3" enemas were given with no results and twelve hours after admittance the patient was practically in the same condition as when he entered, so the diagnosis of intestinal obstruction was made, the exact type of which was not known, and an operation decided on Because of the good condition of the patient and the lack of marked abdominal symptoms, some physicians who saw the patient believed the condition to be an acute catarrhal appendicitis with paralytic ileus

Operation—An incision was made in the mid line of the abdomen. The appendix was normal, but the cecum and ascending colon were markedly distended. The small intestine was run through, but no obstruction was found The transverse colon was distended but the colon below the splenic flexure was collapsed In the lower border of the diaphragm, just to the left of the median line, was a hole large enough to admit the finger tip, in which a knuckle of the descending colon was bound down so firmly by adhesions that it was deemed safer to let the obstruction alone, and do a lateral anastomosis between the portion of the colon proximal to the obstruction and the sigmoid This was done in the usual way A drainage tube was inserted in the left side of the abdomen, the peritoneum and fascia were closed with continuous catgut, and the skin was sutured with interrupted silkworm gut

Postoperative History—For four days after the operation the patient had a temperature of 99 8 to 102 F per rectum, and on July 30, five days after the operation he had a bowel movement He then made an uneventful recovery

The points to be considered in this case are:

1 The long time (ten years) elapsing between the time of injury to the diaphragm and the occurrence of the hernia

2 The relatively few symptoms of intestinal obstruction and its close resemblance to appendicitis; also the good general condition of the patient, which is not usually seen in intestinal obstruction, and the fact that the patient recovered after being ill six days with an intestinal obstruction, in which condition the mortality is very high after forty-eight hours' duration.

100 State Street

ACCIDENTS DUE TO SWIFTLY MOVING MACHINES, AND THEIR AUTOMATIC RATIONAL PREVENTION

ESPECIALLY AS CONCERNS INDUSTRIAL CONDITIONS

WILLIAM J MANNING M D
Medical Officer Government Printing Office
WASHINGTON D C

The conscientious physician always seeks the removal of the cause of any disease that may come under his treatment when that is possible, rather than the treatment of mere symptoms that tend to recur so long as the cause remains.

We may apply this sound principle with practical results to the prevention of accidents arising from swiftly moving or power-driven machines If manufacturers or factory owners should have passed in their respective states, a provision or clause in any law as concerns liability between the employer and employee the respective state insurance commissioners to pass on all details of bond application, based on the following, or a similar method.

The manufacturer, builder, or agent of the machine shall place an indemnity bond with an approved surety company, to the amount of, say, 5 or 10 per cent of the total cost of the machine, which bond is to run during the estimated life or period of usefulness of the mechanism, as shall be agreed on, such bond to be drawn on by the employer or manufacturer after an accident, for the purchase of safety devices, bulwarks, mechanical guards, etc, to be placed on the specific machine so covered

This method should insure to the builder or agent of the machine

1 The avoidance of the moral responsibility of maiming employees for life

2 The saving of large treasure if state governments should adopt such a measure, that is wasted at the present

time and otherwise would continue to be wasted, so far as prevention and a repetition of the accident are concerned.

3. Safety measures that are automatic in their function and operation, both obtained at a minimum of cost.

4. Relief of courts of law from the burden of time and expense in passing on the party at fault—the manufacturer as an employer, or the employee through negligence.

5. Universality and automatism of action and scope, whether the machine is a clattering loom in a New England cotton factory, a fast perfecting printing-press in New York City, or a threshing-machine on some Western farm.

6. Ingenuity of the mechanician or draftsman brought into play at the erection or construction of the machine, in order that the builder or agent may receive low rates on his bond or insurance for a well-protected machine, as is the case of a house well protected from fire—resulting in a low rate of insurance.

7. The minimum expense involved at the time of the construction of machinery in covering all dangerous points.

To the manufacturer or employer it should insure:

1. Relief from mental anguish, responsibility and worry after an accident.

2. Avoidance of expense and reduced profits on his output as the sequel to an injury.

3. Tranquillity of mind, in that defects or dangerous parts of machines that may and do cost him treasure will receive attention hereafter, as well as increased quantity and quality of output—minus damages—that he has apparently heretofore lost sight of.

4. Very little, if any, increase in the cost of machines to him, owing to growing competition and the low cost to the builder of safeguarding machine when it is under construction.

5. The right to sue builder of machine at any time to recover the sum paid for the mechanism, the law holding the sale or transaction void unless bond has been properly filed in the first instance.

To the employee or mechanic it would insure against:

1. Physical pain and misery.

2. Reduced earning capacity.

3. Death, or invalidism for life.

4. The receipt of possible injuries to limbs for which mere money could not hope to offer adequate compensation.

EXTENSIVE WOUND OF THE EYE BY AN INFECTED INSTRUMENT

RECOVERY WITH RETENTION OF VISION

EDWARD ARMITAGE, M.D., M.R.C.S. (Eng.)
Government Physician for the District of West Kau, County of Hawaii
NAALEHU, T. H.

History.—Between 3 and 4 p. m., May 16, 1910 while Iopa Kahula, an 8-year-old Hawaiian boy, was engaged in cutting an old leather whip-lash with his knife, the lash being suddenly divided, the blade of the knife penetrated his right eye. His mother, on seeing blood and water flowing from the wound, carried him into the house, laid him on a couch, and bound up the eye with a handkerchief. Between 5 and 6 p. m. the same day, I was summoned to see the boy.

Examination.—I found that there was an extensive, incised wound of the sclerotic and cornea, and felt convinced that the eye would eventually be lost. However, I determined to make an endeavor to save it and adopted the following plan of treatment.

Treatment.—There being no apparent prolapse of the iris, the eye was thoroughly irrigated with a solution of mercuric chlorid, 1 to 1,000; a solution of atropin, containing 1/50 grain was instilled; the eye was covered with a thick layer of cotton-wool and bandaged; the strictest repose in the recumbent position and the most complete quiet were enjoined.

Naalehu is specially renowned for two climatic features, viz., prevalence of high winds and accumulation of dust; the boy's house was close to the dusty highroad, and was certainly not much cleaner than that of the average poor Hawaiian. Throughout my district of West Kau, there was no hospital or semblance of hospital accommodation; and for this reason I decided to examine and dress the eye but once a day, while I most forcibly enjoined on the parents and on the boy himself, that on no account was the dressing to be touched; that the boy was to lie on his back constantly; that soft food only was to be given to him, in order to prevent, as far as possible, the movement of the facial muscles during mastication, and that he was to be brought, still in the recumbent position, lying on a wagon, every morning to my office, which was situated not far from his residence.

Every morning the boy was brought to my house, the wound and eye were carefully irrigated with a 1 to 1,000 solution of mercury bichlorid, four drops of a 1 per cent. solution of atropin sulphate were instilled into the right eye, and one drop of the same solution into left eye; then, both eyes were carefully padded over with cotton-wool and carefully bandaged. After the first day or two, 10 grains of sodium salicylate were administered every two hours, throughout the progress of the case.

Entering the sclerotic, 1 mm. below the center of the lower border of the cornea, in the "dangerous zone" of Nettleship, the blade of the knife divided the sclerotic and cornea, emerging from the latter 1 mm. below the upper and inner border of the cornea, thus making a somewhat curved incision, which was distant 1 mm. from the inner border of the cornea, the length of the wound being 6 mm.

May 17 there was keratitis and iritis; no pain, but some swelling of the eyelids; the wound appeared to have closed satisfactorily. May 20 the boy could not see light with the right eye, evidently owing to the previous effusion of blood, and I noticed after the first day or two that the pupil had taken on a grayish tinge, indicating the presence of cyclitis. The above symptoms gradually subsided, and on May 26 the boy was able to see me with the wounded eye for the first time since the injury. There was no pain on slight pressure on either eyeball, while the corneal wound was completely healed with a leukoma along its borders. May 30 I discontinued the use of the 1 to 1,000 solution of mercuric chlorid and commenced to irrigate the eye with a sterilized solution of boracic acid. May 31 I instilled three drops of a 1 per cent. solution of atropin into the right eye and continued the one drop in the left eye. On June 6 the left eye was exposed, but the one drop of 1 per cent. solution of atropin was still continued every morning. No unpleasant effects have followed from the prolonged use of the atropin, and it was only on inquiry on June 9 that I elicited from him the statement that his mouth was dry. June 12 the boracic acid lotion was changed for sterilized physiologic saline solution, and two drops of a 1 per cent. solution of atropin were instilled into the right eye, the drop in the left eye being continued. The sodium salicylate, 10 grains every two hours, was continued as before. June 13 I supplied the patient with a pair of orange-colored spectacles, in order to cut off the influence of the actinic rays of the spectrum. The bandage was discontinued, but a piece of cotton-wool was placed over the right

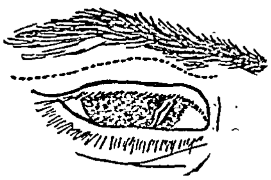

Fig. 1.

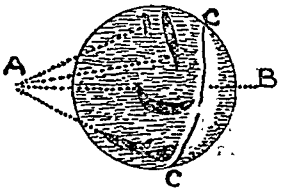

Fig. 2.

Fig. 1.—Eye of patient, after sketch made July 11, showing scar and leukoma; dotted line, vein on lid.

Fig. 2.—Diagram of the cornea (Sept. 23, 1910); black spots (*A*) indicate apertures in stretched iris; white streak (*B*), scar and leukoma; line (*C*), blood-vessels supplying cicatricial tissue.

eye, behind the spectacle glass. He was now allowed to sit up. June 19 one drop of solution of atropin was instilled into each eye, and June 24 the instillation of the solution of atropin into the left eye was discontinued. June 27 the use of the 1 per cent. solution of atropin was discontinued in the right eye. July 4 I made a measurement of the cicatrix and of the leukoma with the curved strabismometer, and July 11 made a sketch of the eye (Fig. 1).

The cicatrix of the incision presents a beautiful linear scar bordered by two blood vessels, and by the leukoma which at its widest part was then 2 mm. in diameter; the length of the corneal cicatrix was 5 mm. August 25, the boy not having come to see me previously during this month, I made an ophthalmoscopic examination of his right eye.

No details of the fundus were to be made out by either direct or indirect examination, but oblique focal illumination showed that, since the discontinuation of the atropin, the iris had been drawn in on all sides toward the cicatrix, completely covering the pupil, but presenting within its texture several apertures through which good vision was obtained (Fig. 2). There was no pain or inconvenience whatever, and no tendency to staphyloma.

September 22 the leukoma measured 1 mm. at its widest part. The eye, apart from the anterior synechia and the scar, is normal in appearance. Distant vision with the right eye is apparently perfect, the near vision is somewhat difficult to determine, as the patient is unacquainted with the alphabet, but he takes pleasure in looking at, and recognizes the objects in picture books, though when interrogated he says that he sees "small" with his right eye.

A peculiar feature in connection with this case is the development of a vein, proceeding from the inner border of the upper eyelid, along the median portion of the lid towards the outer canthus. Possibly this communicated with the angular vein and so with the ophthalmic vein.

Taking into consideration the very successful results which have followed the treatment of the above case and the good vision which the patient possesses with his right eye, I do not propose to perform any operation on the iris at present. At present I am instilling three drops of a 1 per cent. solution of atropin into the eye daily.

There is an old and time-honored maxim which asserts that "meddlesome midwifery is bad." How much worse is unnecessary interference in the healing process of such a delicate organ as is the eye!

CEREBROSPINAL FLUID OF ANOMALOUS CHARACTER IN A CASE OF INTRA-SPINAL TUMOR

C. M. COOPER, M.B., Ch.B.
SAN FRANCISCO

Since the cerebrospinal fluid is frequently examined as an aid to the diagnosis of cerebrospinal disease it seems wise that any anomalous finding should be reported.

The fluid withdrawn under a pressure of 160 mm. of water, from a patient without fever, and with signs of a localized segmental lesion of the cord, had the following characters:

Macroscopically, it was clear and of a yellowish-brown color, looking like the clear serous fluid that is aspirated from pleural or peritoneal effusions. On standing a well-marked cobweb coagulum formed. The Noguchi and Nonne globulin tests were strongly positive, thick precipitates occurring. The Wassermann complement reaction was negative in the fluid as in the blood.

Microscopically, practically no cells were to be found either in the centrifugalized fluid or in the coagulum. No bacteria could be detected.

Dr. Hyman, who later operated on the patient, and I came to the conclusion that we were dealing with a case of chronic compression of the cord, probably due to an intraspinal tumor, but an explanation of the findings in the cerebrospinal fluid did not suggest itself. At operation a strongly marked edema of the membranes was found below the site of the tumor (an angiosarcoma). The transudate character of the fluid seems thus explained.

A similar finding, then, would suggest the presence of a compressing agent plus the probable concomitant occurrence of edema of the membranes, and would warn one to beware of the false localizing signs that may occur with such edemas.

SAPHENOUS VARIX SIMULATING FEMORAL HERNIA

ALFRED H. NOEHREN, M.D.
BUFFALO, N. Y.

To the well-known saying, "The man who never makes mistakes in diagnosis never does autopsies," I would add "and never operates." Of all the surprises I have ever had, either in operations of my own or in those at which I assisted, the case I am about to describe was the greatest. The rarity of the condition found and the importance of differentiating it from femoral hernia are my reasons for publishing this case.

History.—On Oct. 11, 1910, I was called to see Mrs. K., a woman of 37, mother of seven children, the youngest being 3 years old, who had always been in good health and had worked hard all her life. She complained of crampy pains all over her abdomen, but most severe on the lower left side, together with continual rumbling of gas. As she had been constipated for a few days, she had taken several doses of castor oil. These increased the pain, although they brought on a fairly good bowel movement. There were no other complaints.

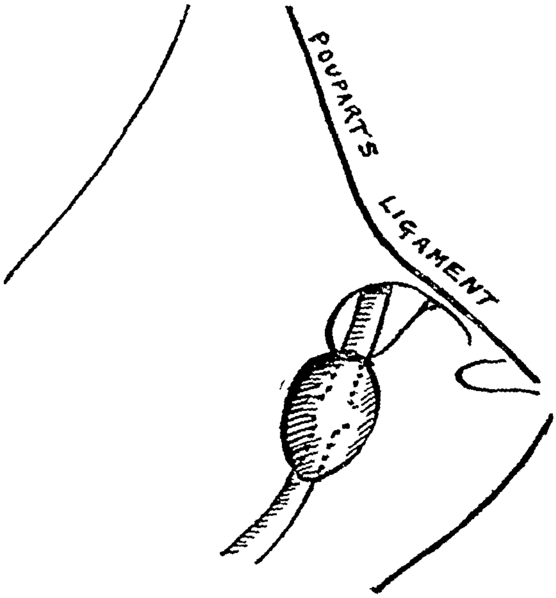

Diagram of saphenous varix simulating femoral hernia

Examination.—Temperature was 98 F.; pulse, 112. The abdomen was not tender, was soft, there were no masses felt or swelling noticed. Just below the saphenous opening on the left side, however, was a swelling about as large as a walnut. It was not tender, was easily reducible, especially when the patient lay down, and gave a most decided impulse on coughing. The patient said she had noticed this swelling ever since the birth of her last child and that it had never given her any trouble. I made a diagnosis of femoral hernia and told the patient it would be well to have it operated on, telling her of the danger of strangulation, etc. Her abdominal cramps I attributed to the cathartic and treated her accordingly.

Three days later I was called again. The abdominal pains had grown worse, especially on the lower left side, and radiated down the left thigh. She had frequent soft stools and the rumbling of gas was marked. Temperature was 100 F.; pulse, 124. Peristaltic waves could be seen over the lower left abdomen, where there was also tenderness and more resistance than on the right side. The hernial mass was a little larger, was tender, and was no longer reducible. Operation was now most urgently advised, but absolutely refused. During the day, the temperature rose to 102.6 F. and an indistinct mass could be felt in the lower left quadrant of the abdomen. On the evening of the next day, the bowels moved, but with much difficulty and straining. There was considerable resistance in the lower left side of the abdomen and the entire abdomen was moderately swollen and tympanitic, especially over the course of the colon. The patient felt nauseated and vomited a little bile. The hernial mass was tense, tender, and flat to percussion. Temperature was 102.2 F.; pulse, 124. Operation was now insisted on. The patient was taken to the German Deaconess Hospital at once, where I operated that same evening.

Operation.—An incision was made over the supposed hernial swelling and large enough to do a radical operation for the cure of femoral hernia. Imagine my surprise on dissecting out the mass to find that it did not emanate from the saphenous opening at all, but was continuous on either end with the internal saphenous vein just below its emergence from the saphenous opening. It formed a sacculated pouch springing from the anterior wall of the vein. The vein was tied off above and below the tumor and the latter removed. On opening, it was found to contain a fairly fresh unorganized blood-clot and the wall of the pouch was a dilatation of the wall of the vein. There was no hernial sac visible, neither was the femoral ring abnormally large; nevertheless I sutured Poupart's ligament to the pectineal fascia with one catgut stitch, thus preventing the possibility of a future hernia or the recurrence of one that might have slipped back into the abdomen. The wound was closed with interrupted silkworm-gut sutures. Examination under anesthesia now revealed a large infiltrating mass occupying the pouch of Douglas and extending upward into the left side of the abdomen. I decided to terminate the operation at this point and await developments.

Subsequent History.—The patient ran an irregular temperature ranging from 99 to 103 F. for ten days, after which it suddenly came to normal, where it stayed during the remaining eight days that she was in the hospital. During this time, the pelvic mass became gradually smaller and on her discharge could barely be felt. As it gave no symptoms and seemed to be gradually disappearing, the patient was tentatively discharged from the hospital.

In looking over the literature, I find a saphenous varix in this location a vary rare occurrence. I could find no case reported in the last three years. Although varicosities are common enough in the long saphenous vein, they are uncommon in this situation. According to MacCready's statistics quoted in von Bergman's and Keen's text-books on surgery, a saphenous varix was mistaken for femoral hernia nine times as against forty-seven times that abscess and one hundred and fifteen times that enlarged lymphatic glands were the cause of a mistaken diagnosis.

So much for a simple varix. But to find such a tumor, with impulse on coughing and easily reducible, after three days no longer reducible and tender in a patient with rising temperature, abdominal cramps, swollen tympanitic abdomen, and the other symptoms I have mentioned, was an unusual coincidence.

The explanation was simple enough after the operation. The varix had become thrombosed during the three days and the temperature and abdominal symptoms were due to the pelvic exudate.

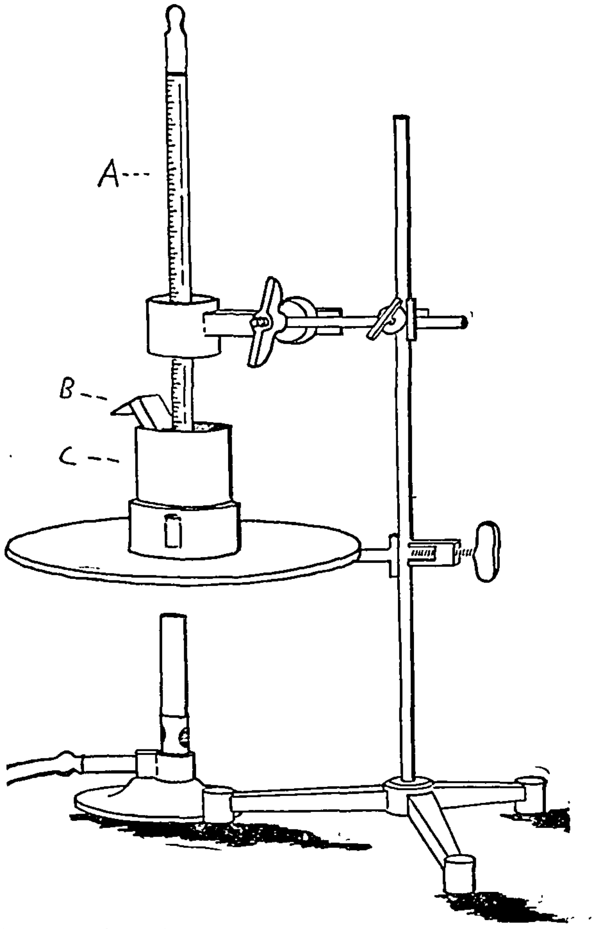
519 East Utica Street.

A SIMPLE APPARATUS FOR ACCURATELY FIXING BLOOD-SLIDES BY HEAT

GEORGE B. LAWSON, A.M., M.D.
ROANOKE, VA.

In fixing blood-slides by heat, one finds that the results of the copperplate method are so inconstant that it is difficult to get a good specimen unless one keeps in constant practice. There is no way of determining the exact amount of heat used or of keeping the heat regular. I have devised the following simple apparatus for office and laboratory use:

As shown in the illustration, an ordinary laboratory standard supports an iron dish, C, resting on an asbestos plate, under which is a gas burner. This iron dish is easily made by screwing a two-inch nipple into a pipe cap. This dish is filled with petrolatum, into which is sunk a small, thin copper cup so that the end sticks out as shown at B. This cup is just large enough to admit with ease the glass slide. In the petrolatum is sunk the bulb of a thermometer, A. The exact temperature is registered by the thermometer. The slide may be introduced by using a small copper strip bent at an angle at the ends; and when the blood is sufficiently heated the slide and copper strip are withdrawn. With Ehrlich's stain I have obtained the best results by heating to 280 F. for seven minutes.



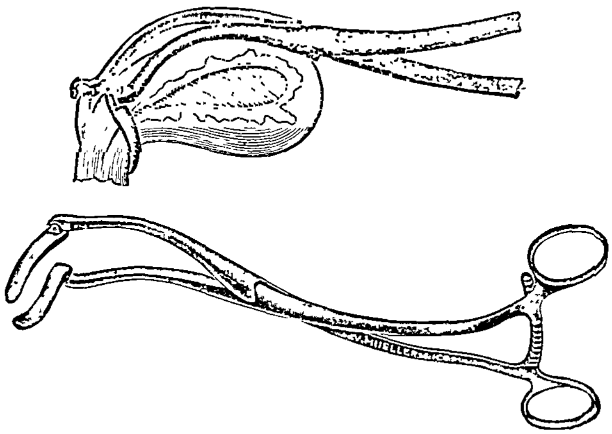
Apparatus for fixing blood-slides by heat. A, thermometer for registering amount of heat; B, copper cup for holding blood-slide; C, dish containing petrolatum in which cup with blood-slide is immersed.

The disadvantages of this apparatus are that it requires constant attention. The advantages are that the slide may be accurately heated, and this may be done by one's untrained office assistant, whereas by the copperplate method one can hardly get constantly good results no matter how well one is trained.

AN IMPROVED UTERINE CLAMP AND RETRACTOR

A. MILES TAYLOR, M.D.
SAN FRANCISCO

The clamp illustrated is one which I have devised, believing that it will serve the purpose for which it is intended better than any clamp heretofore available. I find it very useful in all cases in which it is desired to elevate and hold up the uterus. Being devoid of teeth it does not injure or macerate the parts. The curves of the instrument allow it to fit around the uterus and it is not in the way in operating on the uterus or appendages from any side. In some cases it may be used as a retractor. The jaws of the instrument are bent so as to grasp and surround the neck of the uterus without in any way injuring it. The jaws being on a swivel are not apt to produce sufficient pressure to do damage.



The uterine clamp and retractor, showing it applied to the uterus.

I have used the instrument in abdominal hysterectomies, removal of the appendages, in operations for ovarian lesions, shortening of the round ligaments, ventral fixation, removal of interstitial and subperitoneal fibromyomas, and in bringing up the uterus to expose the bladder.

Therapeutics

THE LOCAL APPLICATION OF DRY HOT AIR

The general practitioner will never be able to apply personally the major elements of physiologic therapy to any great extent because of the elaborateness of the plant required, but some of the minor elements can be perfectly utilized by the general practitioner, and most gratifying therapeutic results obtained. The local application of dry hot air is one of the most useful of them.

There are on the market several forms of apparatus for its application, all of which will do good work. In order to be efficient an apparatus must be capable of producing 400 degrees Fahrenheit in fifteen minutes at the outside, and of maintaining this temperature indefinitely. In order to be useful to the general practitioner these machines must also be easily portable. They may be heated by gas, gasoline, alcohol, or electricity, but one that is to be used in general practice should be supplied with a gasoline attachment, whatever other heating agent is usually employed, as the gas-pressure in some houses is not sufficient to produce an adequate degree of heat, electricity is available in only a few houses, and alcohol is not generally satisfactory for several reasons.

Preparation of the patient for the application is simple, consisting merely in covering the part of the body to be treated with three thicknesses of loose-meshed Turkish toweling, so as to secure intimate contact between wrapping and skin. If the perspiration which is induced as soon as the heat strikes the skin, is allowed to remain on the skin during a treatment, it will soon boil under the influence of the intense heat and blister the patient. These wrappings absorb it as soon as it is formed, the heat immediately vaporizes it and it rapidly diffuses itself out of the wrapping.

Directions for the general operation of the machines, are furnished by the manufacturers. Complete treatises on thermaerotherapy can be obtained by those who take more than a passing interest in it.

The physiologic effect of the dry hot-air application is produced in two ways: first, by thermic irritation of the numerous nerve-endings in the skin, and second, by the actual raising of the temperature of those portions of the body in immediate contact with the heat.

Irritation of the nerve-endings of the skin results, by reflex action, in (1) marked dilatation of the capillary areas, hence greatly increased blood-supply, (2) enormously increased functionation of the sweat-glands, hence increased local elimination, and (3) acceleration of the cell nutrition and function through reflex stimulation of the spinal centers. The raising of the temperature, *en masse*, results in acceleration of the chemical reactions constituting the cell metabolism of the part. It will be observed that the combination of these influences result in increased physiologic resistance of the tissues affected and acceleration of the process of repair of damaged tissue elements.

The sphere of action of this application, then, is in the treatment of pathologic conditions which are strictly local in character, and which can be happily influenced by increasing the local physiologic cell resistance and the local nutritional, absorptive, and eliminative functions. Such conditions obtain in many diseases encountered by the general practitioner but it will suffice to mention three which illustrate the different types of cases in which the local dry hot-air application is most useful. These three are (1) sprains, (2) most cases of true rheumatism in which but one or two joints are involved, and (3) local septic infection of the extremities before the process has involved the lymphatics connecting the affected part with the trunk, and in which the general toxemia resulting from the local lesion is not profound enough to overwhelm the organism as a whole.

SPRAINS

In an uncomplicated sprain the lesion consists simply of a traumatic solution of the continuity of soft tissues about the affected joint, accompanied by severe pain probably due to congestive irritation of lacerated nerve fibers. The therapeutic indications are (1) to relieve pain, (2) so to influence the trophic functions as to secure the quickest possible repair, and (3) to promote absorption of the exudate.

Increase in the physiologic resistance of cells is not called for in this condition, but acceleration of the nutritional, absorptive and eliminative processes are indicated; practically clinical experience demonstrates that the local dry hot-air treatment is well qualified to satisfy the requirements. If a sprain is put under treatment by this agent within three or four hours after the injury has been sustained, the pain will be relieved within half an hour, and all traces of the trouble will usually have disappeared within forty-eight hours. If the case is three or four days old, however, and exudate is present to any great extent, complete removal of disability may require from two to three weeks; but the pain is usually susceptible of the same immediate relief as in early cases.

The local dry hot-air application also serves as a valuable diagnostic test in these cases, by informing us as to whether or not a fracture coexists. When a fracture complicates the case the treatment will usually relieve the pain somewhat; less frequently it will not relieve it at all, and sometimes it makes it worse. Its power to effect practically complete relief of pain is so universally observed when the lesion is uncomplicated, that failure to produce such relief is almost positive evidence that a fracture is present.

RHEUMATISM

In this affection we have an acute, infectious, inflammatory process, probably specific in nature, characterized by intense pain and more or less effusion, both probably due to local toxin irritation. The therapeutic indications, then, are to increase the physiologic resistance of the invaded regions and to accelerate elimination from this region. A sufficient increase in the physiologic resistance of the threatened cells would stop the invasion and immediately decrease the number of the invading organisms, which would immediately lessen the virulence of the toxemia attributable to them; accelerating elimination would still further lessen toxemia; and dilating the capillary areas would relieve blood-vessel spasm and whatever stasis of blood-vessel contents might be dependent thereon.

Clinically, dry hot air demonstrates its capacity for producing all these effects and some cases of rheumatism can be cured by it alone. The proportion of such cases, however, is not large enough to justify confining our therapeusis entirely to this agent, and salicylic acid, in some form and in adequate dosage, should always accompany the dry hot-air treatment. When these two remedies are used in combination, however, there result (1) immediate relief of the pain, however severe, (2) a shortening of the duration of the disease to from five to ten days, (3) a lessening of the likelihood of cardiac involvement because the rapidity with which control over the condition is obtained diminishes the time period during which the infection threatens structures other than those originally affected. When this picture is compared with that resulting from ordinary antirheumatic therapeusis, the beneficent rôle which dry hot air plays in the management of this disease becomes at once apparent.

This happy picture, however, applies only to uncomplicated cases in which but one or two joints are involved, cases in which the general toxemia is not severe enough to depress the general nervous system seriously. When the general toxemia is very severe, the development of a satisfactory recovery will necessitate invoking the powerful influence on general metabolism and elimination of the general or body application. The local application will be just as effective in relieving pain but the relief will not last as long and it will not be as complete. Neither does this picture apply to cases of arthritis deformans, neuritis, inflammatory joint or bone lesions, or malignant disease, which are so often misdiagnosticated as rheumatism.

The foregoing implies that salicylic acid sustains more or less the relation of a therapeutic specific to rheumatism. Now it has become quite the fashion in recent years, on the part of some eminent clinicians, to assail this belief which has become so firmly grounded in the mind of the average practitioner by his years of bedside experience with the drug—to maintain that it is purely and simply a pain-reliever. To one who habitually sees much of arthritis deformans in its early stages and of neuritis, a possible explanation suggests itself for these beliefs in the number of instances in which really eminent clinicians mistake neuritis and arthritis deformans in its early stages, for rheumatism, and prescribe salicylic acid. Of course the patient derives only more or less temporary relief of pain from this procedure; salicylic acid exercises no special curative effect on these conditions. Then again, however specific a curative agent may be, adequate dosage is required in order that it may manifest its specific properties, and salicylic acid is prescribed with astonishing frequency, in ludicrously insufficient quantities.

The last word has by no means yet been said regarding the specificness of salicylic acid as a remedy for true rheumatism. As a matter of fact, it cannot be said until the specific causative factors of the disease have been isolated and defined, so that a specific definition of rheumatism may be formulated, and we may be sure that we all mean the same thing when we use the term.

LOCAL SEPTIC INFECTION

This is another condition in which the physiologic influences of local thermaerotherapy are most appropriate. The disease process is of distinctly local origin, it involves a lowered vitality, or lack of physiologic resistance on the part of the involved tissues, and in the majority of cases it occurs on one of the extremities at a considerable distance from the trunk.

The therapeutic indications are (1) to increase the physiologic resistance of the invaded structures, whereby the pabulum of the micro-organisms is so modified as to inhibit their development, lessen the virulence of their toxic emanations, and finally to accomplish their destruction; and (2) to eliminate as rapidly as possible the toxic products already present in the affected parts.

A comparison of the physiologic action of this therapeutic agent with the pathology and therapeutic indications present in this ailment, explains at a glance why dry hot air would be expected to inhibit helpful attributes, and the clinical findings again bear out most happily the theoretical deductions. If a case is put under treatment before suppuration has been established and before the infective process has invaded that portion of the limb (lymphatics or other structures) immediately contiguous to the trunk, the pathologic phenomena will usually be abruptly arrested and the inauguration of convalescence will coincide with the first treatment. If suppuration at the point of infection has been established, the destructive process will become sharply and quickly localized when, by a stroke of the knife, the pus can be evacuated and the case brought to a rapid and satisfactory termination. If, however, the lymphatics at the junction of the affected part with the trunk are involved or if general toxemia is severe enough to seriously depress the central nervous system, the local application will have to be either superseded or accompanied by the general or body treatment.

Among other conditions in which the local application of hot air is more or less useful are pneumonia, pleurisy, acute gout, synovitis, fibrous ankylosis, some cases of neuritis, varicose ulcers, and sluggish healing processes not due to malignant, tuberculous or syphilitic infection. The physiologic action of hot air is definite and constant and hence constitutes a reliable guide as to what sort of pathology will yield to its influence.

SATURDAY, DECEMBER 31, 1910

[The large amount of space occupied by the index this week makes it necessary to omit some departments and to curtail others.]

THE CAUSE OF GENERAL PARESIS

Softening of the brain, general paralysis of the insane, or, in its more modern terminology, general paresis, has become a wide-spread affection. In the therapeutic attack on it we stand helpless, and therefore any clues that may be offered regarding the factors that assist in its development are eagerly grasped at in the hope that they may lead to its conquest.

Since Fournier's time the most widely accepted belief has been the syphilitic origin of paresis. Many English psychiatrists have maintained, and some even now hold, that sexual excesses, especially sexual aberrations, fellatio in particular, may cause the disorder in the absence of syphilis, but the more careful analysis of histories, the newly acquired knowledge concerning pseudoparetic syndromes in brain tumor, in arteriosclerosis, in multiple sclerosis, in alcoholism, plumbism and allied toxemias, and particularly the utilization of the cytologic examination of the spinal fluid with the Wassermann test of both blood and spinal fluid—these have all served to establish more firmly than ever the dictum, "without syphilis no paresis."

But even when this is said, the goal has not been reached, for the newly explored field of comparative psychiatry shows some very striking anomalous conditions, which compel one to stop and analyze the factors, especially since it would appear in the light of these newer facts that some other element than syphilis alone is essential.

It was but natural that alcohol should have been thought of as the chief contributory element in this etiologic chase. The early French psychiatrists so taught, and the belief is fairly universal that alcoholism and syphilis are the necessary elements. But we learn of the high percentage of paresis among peoples such as the Japanese, who have a low percentage of alcoholism and a high percentage of syphilis. Conversely, recent studies of the native peoples of North Africa—Mohammedans for the most part, and non-alcoholic—show that general paresis is extremely rare among them, in spite of the fact that from 60 to 70 per cent. of the population of some regions suffer from syphilis, all stages being represented.

Only a few years have gone by since it was announced that the cause of paresis was to be found in a definite bacterium. Originally explained as a primary infection, the rôle of Ford-Robertson's diplococcus has fallen from that of a possible infectious factor secondary to that of an ordinary laboratory contamination. The possibility of light has been shut off in this direction.

Can comparative psychiatry throw some light on the subject? This question seems to be answered in the affirmative in a recent communication by Rudin,[1] based on some studies of paresis made on the native races of Algeria. Rudin has gone very completely into the much-discussed question concerning the presence of paresis among these races, and has apparently established the fact that for the present state of occupation and culture the native races of Algeria, notwithstanding a 60 to 70 per cent. infection with syphilis, are free from paresis, and the evidence further points to the fact that syphilis is no new disorder in Algeria, but was probably introduced there in epidemic form about the same time that it showed itself in Spain and Italy, *i. e.*, in the post-Columbian period.

Rudin looks on the process of civilization as the answer to the problem, which he looks at from two points of view.

In the first place, the severe stress of higher civilization and race culture shows itself more particularly in the nervous system. Modern modes of life place particularly heavy burdens on the nervous energy and the nerve centers. One result of the struggle with syphilis and excessive nerve-strain combined is paresis. In primitive peoples, in whom the latter factor is absent, the brain does not give way, and syphilitic lesions are more common in those parts of the body more exposed to physical wear and tear, namely, the skin and the bones.

Secondly, the advance in superiority of the white races, which has come about largely through increasing complexity of the nervous system, has entailed a high percentage of hereditary shortcomings. The studies of Julius and Arndt have shown, contrary to the usual belief, that hereditary factors are very prominent in the ascendants of paretics. It thus becomes plain that, after all, paresis, although primarily a result of infection, brings into high relief the general problem of the relation of soil to the processes of destruction. Given a brain not deteriorated by hereditary factors and not called to work at the high pressure forced on it by modern factors of civilization, a syphilitic infection rarely leads to a paretic breakdown. This is the final conclusion of this interesting study of Rudin in the field of comparative psychiatry.

A LITERARY CENTENNIAL OF MEDICAL INTEREST

This year, as the hundredth anniversary of the death of Charles Brockden Brown, one of the earliest of our American novelists, should not be allowed to pass unnoticed among physicians. Brown died from tuberculosis at the early age of thirty-nine. He was one of the men who, like John Addington Symonds and Robert Louis Stevenson, refused to give in to the disease, continued his work bravely, fought off the inevitable as effectively as possible and succeeded in accomplishing a good life's work in spite of his malady. Had he been a "quitter," tuberculosis would probably have taken him much earlier in life and with nothing done.

The story of his career has a therapeutic interest for those who have to do with tuberculous patients. There is an additional reason for medical interest in him, however, for Brown must be considered an important contributor to medical historical literature. In one of his stories, "Arthur Mervyn," he has given us probably one of the best descriptions of an epidemic ever written. It is a vivid picture of one of the awful epidemics of yellow fever which at the beginning of the nineteenth century used to rage in Philadelphia every few years.

We have, by the way, a series of descriptions of epidemics which were written by non-medical men, and which are classics in literature. Thucydides' description of the plague at Athens, Boccaccio's account of the Black Death in his introduction to the "Decameron," Defoe's "Journal of The Plague Year in London," are masterpieces, each in its own way. Brown's description of the Philadelphia epidemic has been placed beside these by Prof. John Erskine in his volume on "The Leading American Novelists." He says that "Brown's was the realism of the journalist. He had an instinct for headlines with the gruesome details, diagrammed and illustrated."

Now that we have reached a point at which we seem to be able to control the spread of epidemics, and now that the history of epidemic diseases begins a new chapter, the old chapters retain at least a historical interest. It is hard now to realize the awful condition of affairs that used to recur in Philadelphia every few years from the introduction and spread of this disease, now regarded as tropical or subtropical. As a matter of fact, however, during the late eighteenth century and early nineteenth century, not only Philadelphia, but New York and even Boston suffered severely from yellow fever. Indeed, the disease occurred so frequently in Philadelphia and worked such ravages among the local population that the question of abandoning that city is said to have been seriously discussed at one time during the first quarter of the nineteenth century, because the site was supposed to be almost hopelessly insanitary. In the intervals, malaria raged there with special virulence, showing that there were abundant opportunities in the neighborhood of the city for the development of mosquitoes of all types. The Philadelphian Rush was an authority on yellow fever, while the elder Pepper, also a Philadelphian, was considered to have great experience with malaria. In another half century or more these diseases will have receded still farther from our horizon. Then Brown's realistic description of the epidemic which he witnessed will be a valuable original document—all the more valuable because it will show the triumph of sanitary science over what seemed to be hopeless conditions.

THE INDEX

With this issue we present the semiannual index. We call attention thus prominently to this feature of THE JOURNAL because we are continually impressed with the fact that the tremendous labor connected with it is not appreciated, nor is the practical value of the index realized, except by very few of our readers. It is worthy of emphasis that this is not only an index of the articles which appear in our own journal, but an index of most of the original articles that have appeared in most of the medical journals of the world for the last six months. In other words, the semiannual index issued with the last number of each volume of THE JOURNAL is an index of the progress made in medicine, covering all its phases, in every part of the world. As will be noticed, the matter is indexed both by title and by subject, being fully cross-indexed; and in addition there will be found a complete authors' index.

Another point to which attention should be called is this: The index is reprinted in pamphlet form, in which are included also the titles which have appeared week by week in THE JOURNAL. The advantage of this pamphlet,[1] the "Guide to Current Medical Literature," is that it is more easily handled than is the file or bound volume of THE JOURNAL, and thus the references are made more accessible.

Current Comment

SALVARSAN ("606")

In the Pharmacology Department of this issue,[2] appears an interesting and valuable report by the Association's laboratory on the chemistry of Salvarsan ("606"). While much has been written about this new remedy for syphilis, particularly about the technic of its administration, comparatively little has been said regarding the chemical identity of the drug. The report of the Association's chemists is a timely one and will enable physicians to follow more intelligently the directions for preparing the injections. The description of Salvarsan, which is given in concise language, makes clear the chemical properties of the substance, a knowledge of which should be possessed by those who purpose using it. As the report states, the investigation of Salvarsan was taken up at the request of the Council on Pharmacy and Chemistry in connection with the inclusion of this product with New and Nonofficial Remedies. This fact calls attention to three things: First, the United States is the only country in which the medical profession has its own body of expert pharmacologists and chemists to conserve its interests and thereby the interests of the public. Second, those manufacturers who consider the suggestion that they submit their products to the Council, for verification of the claims made for them, as a reflection on their probity, should note that those who sell this remedy, which may prove one of the therapeutic achievements of this century, do not hesitate to court the fullest investigation of the product. Third, it makes clear the fact that the Council examines each product impartially and without fear or favor. It is not only possible but probable that the enthusiastic claims which some of the users of this new remedy are making for it will, in the light of future developments, be greatly modified. Nevertheless, whatever opinion may be held regarding the ultimate value of Salvarsan, it is evident that the greater the amount of available information regarding it, the sooner will its true therapeutic status be determined.

THE BAT AS A DESTROYER OF MOSQUITOES

It is said that a Texas county medical society plans to ask the legislature of that state to pass a law protecting bats on the ground that they are efficient destroyers of the mosquito. The general cultivation of bats, even as inmates of homes, is also said to be recommended. No doubt the bat is an efficient insect-destroyer, but it is repulsive to most people, and, like the spider, which is an enemy to the infection-bearing house-fly, or the lizard, which is often tolerated or encouraged among tropical peoples, it is not considered a desirable housemate by the tidy housekeeper of our country. In addition, the bat sometimes carries certain objectionable parasites of its own, such as *Cimex*. Thus, although the bat has its place in the economy of nature and may render us more service than we have been aware of, as a household pet it is hardly fitted to make homes happy, or even altogether hygienic.

GENERAL SHERMAN'S OBSERVATIONS CONCERNING COLDS

A wholesale illustration of the effect of outdoor living in preventing colds is contained in a letter of General Sherman to his wife written from Goldboro, North Carolina, during the Atlanta campaign. He speaks of his men, after having passed through the rigors and exposures of that strenuous campaign, and after being equipped with new clothing, as a fine-looking set of soldiers, brawny, strong and swarthy, a contrast to the weak and sickly-looking men who came to him in Kentucky three years before. He observes: "It is a general truth that men exposed to the elements do not catch cold, and I have not heard a man cough or a sneeze for three months; but were these men to go into houses, in a month the doctors would have half of them. Now the doctors have no employment." A writer in the *Dietetic and Hygienic Gazette* refers to this as a "symptomatic observation worthy of a doctor, but unexpected in so great a general." He says that the general was not making a holiday health speech, but writing a universal cold-cure recipe, for a remedy which is as free as air and as bounteous as the canopy over us, and which any one can procure and use.

Medical News

ALABAMA

The Red Cross on Automobiles.—Forty-seven of the physicians of Birmingham, on the request of the chief of police, have placed on the fronts of their automobiles the Red Geneva Cross, whereby these are given the right of way over other vehicles.

Personal.—Dr. William W. Dinsmore, Decatur, has been appointed supervisor, for the state, of the Rockefeller Commission for Medical Research with headquarters in Montgomery.——Dr. Henry G. Perry, Greensboro, has been appointed general field agent and Dr. J. F. Orr, Littleton, has been appointed field worker.——Dr. James F. Meyers, Decatur, has severed his membership with the Morgan County Medical Society, and expects to locate in Springfield, Ill.——Dr. P. B. Moss has succeeded Dr. E. Marion Mason, Montgomery, as state bacteriologist.

ILLINOIS

Physician Wins Damage Suit.—Dr. Archie W. Barker, Springfield, won the suit in which a patient asked $20,000 damages on the ground that Dr. Barker, in performing an operation for fistula, cut a muscle in such a way as to injure the patient for life.

Dispensary Staff Named.—The Springfield Tuberculosis Association announces the following active medical staff of the tuberculosis dispensary which will be in operation January 1: Drs. Charles L. Patton, John W. Kelly, Charles P. Colby, Samuel E. Munson, Milton G. Owen and George T. Palmer, who has also been elected superintendent. The consulting staff is composed of Dr. Lewis C. Taylor, president of the association and Dr. George F. Stericker.

Cook County Institutions.—The newly elected president of the Cook County Board precipitated a contest for supremacy between himself and the County Commissioners. At present, Dr. Charles F. W. Eberlein, formerly assistant superintendent, has been declared acting superintendent and, acting on orders from the president, has refused to obey the orders of a committee of the County Commissioners to turn the keys over to them.——Dr. Oscar C. Willhite, formerly superintendent of the Cook County Institutions, Dunning, was presented, on December 20, with a silver loving-cup by 200 employees of the institution, in token of their high regard for him. He had resigned rather than obey the order of the new president of the board to discharge two employees without trial. Their alleged offense was abuse of a patient, a charge of which Dr. Willhite declared that he was unable to find reliable evidence.

County Physicians Elect.—At the annual meeting of the Monroe County Medical Society, Dr. Stephen Kohlenbach, Columbia, was elected president; Dr. Arthur F. Schellschmidt, New Design, vice-president; Dr. Louis Adelsberger, Waterloo, secretary (reelected); Dr. Jacob C. Fults, Waterloo, treasurer; and Dr. John S. Sennott, Waterloo, delegate to the State Medical Society.——Champaign County Medical Society held its annual meeting in Champaign, December 8, and elected the following officers: Dr. William Rees, St. Joseph, president; Dr. Lucy A. Exton, Thomasboro, vice-president; Dr. Jennie Lyons, Champaign, secretary-treasurer; and Drs. Albert S. Wall, William L. Gray, both of Champaign, and James S. Mason, Urbana, censors; Dr. John Marten, Tolono, delegate to the state society; and Dr. Thomas J. McKinney, Gifford, alternate.——The thirty-seventh annual meeting of the Northern Central Illinois Medical Association was held in Peru, December 7, and the following officers were elected: Dr. Alfred E. Owens, Princeton, president; Drs. Thomas W. Burrows, Ottawa, and Ezra T. Goble, Earlville, vice-presidents; Dr. George A. Dicus, Streator, secretary-treasurer.——Winnebago County Medical Society, at its annual meeting, held in Rockford, December 13, elected Dr. William H. Fitch, president; Dr. Allen C. Eakin, vice-president; Dr. Frank W. Hanford, secretary-treasurer; and Dr. William E. Park, censor, all of Rockford.——The La-Salle-Peru Medical Society, at its annual meeting in LaSalle, December 13, elected Dr. Samuel G. Mengle, Peru, president; Dr. Walter W. Greaves, LaSalle, vice-president; and Dr. Frederick A. Guthrie, LaSalle, secretary-treasurer.

Chicago

Bequests to Hospitals.—By the will of the late Michael Cudahy, $2,500 is devised to St. Elizabeth's Hospital, and a similar sum to St. Joseph's Hospital.

Fined for Misbranding.—Charles Gilbert Wheeler of the Wheeler Chemical Works, Chicago, is said to have pleaded guilty, December 21, to selling an adulterated and misbranded headache remedy (Anadol). This nostrum was exposed in The Journal, May 21, 1910, in a report from the Association laboratory following an analysis of the stuff by the Association's chemists.

Nurses' Meeting.—The Visiting Nurses' Association of Chicago announces its annual meeting to be held at Fullerton Hall, Art Institute, Jan. 4, 1911, at 4 p. m. Addresses will be made by the president; by Dr. Rachelle S. Yarros on "The Relation of the Visiting Nurse to Settlement Work;" by Dr. William A. Evans on "The Visiting Nurse in the Municipality;" and by Dr. William P. Merrill on "The Personal Note in Social Service."

INDIANA

Local Association Organized.—The physicians of Owensville met November 28, and organized the Owensville Medical Association, and elected Dr. John M. Williams, president, and Dr. Thomas L. Lockhart, secretary.

Provisions for Hospitals.—The will of George F. Johnson, New Jersey, which bequeathed $50,000 to Logansport for the erection of a public hospital in memory of his parents, has been held valid by the courts.——Contracts have been let for the construction of a hospital to cost $60,000 at the Southern Insane Asylum, Evansville.

Tuberculosis Farm Dedicated.—Boehne Farm, the open-air hospital of the Vandeburg County Antituberculosis Society, was dedicated November 27. The farm was donated to the association by Mr. John W. Boehne who also donated $5,000 to the movement. The camp is ready for occupancy and can accommodate at present seventeen patients.

Case Against Unlicensed Practitioner Dismissed.—The case of the state against R. A. Winkleman, Bluffton, charged with practicing medicine without a license, is said to have been dismissed November 28. The defendant conducted a sanitarium for some time, and when charges were filed against him, he sold his institution, and is said to have stopped illegitimate practice.

Specific Instead of General Provisions.—The State Board of Medical Registration and Examination held a conference at the state house, December 15, with representatives of the nine accredited colleges and universities of the state to place a specific construction on entrance requirements of the medical colleges. The present law provides that students seeking admission to a medical school shall have at least two years' work in an accredited college or university.

Personal.—Dr. James W. Milligan, surgeon of the State Penitentiary, Michigan City, has been appointed deputy warden of the institution.——The county commissioners of Marion County, at their meeting, December 16, made the following Indianapolis appointments: Dr. Benjamin S. Potter, superintendent of Marion County Insane Asylum, Julietta; Dr. Clarence L. Marlatt, physician and surgeon at the Poor Asylum; Dr. Thomas L. Sullivan, Jr., physician and surgeon at the Workhouse, and Dr. James R. Anthony, physician and surgeon at the jail.

County Elections.—The Fort Wayne Medical Society, the Medical Society of Allen County, held its annual meeting in Fort Wayne, December 6, and elected the following officers: president, Dr. J. Clifford Wallace, Fort Wayne; vice-president, Dr. Lyman T. Rawles, Huntertown; secretary, Dr. Garrette Van Sweringen, Fort Wayne; treasurer, Dr. Elmer E. Morgan, Fort Wayne; censors, Drs. Samuel H. Havice, Edward J. McOscar and Eric A. Crull, all of Fort Wayne.——Vigo County Medical Society, at its annual meeting in Terre Haute, December 5, elected Dr. Myron A. Boor, president; Dr. Charles N. Combs, vice-president, and Dr. Bennet V. Caffee, secretary, all of Terre Haute.

IOWA

Society Meeting.—At the annual meeting of the Pottawatamie County Medical Society, held in Council Bluffs, December 6, Dr. George A. Spaulding, Avoca, was elected president; Dr. N. Jasper Jones, Shelby, vice-president; Dr. Grant Augustine, Minden, secretary-treasurer, and Dr. Willis F. Pierce, Carson, censor. Council Bluffs was selected as the next place of meeting.

Hospital Notes.—The physicians of Fort Madison, aided by liberal-spirited citizens, have taken over and reopened St. Elizabeth's Hospital founded by the Franciscan Sisters, and have made it entirely self-sustaining.——Dr. David S. Fairchild, Clinton, has written the State Board of Control strongly endorsing the project of establishing a state hospital for epileptic patients.——The State Board of Control has decided to join the State Board of Education in asking the next legislature to establish a psychopathic hospital. This is to be a kind of clearing-house of patients afflicted with various kinds of mental diseases.

MARYLAND

Typhoid Epidemic Checked.—Only twenty midshipmen with typhoid fever remain in the hospital at Annapolis, the rest having recovered sufficiently to go home on leave. No new cases have developed for ten days.

To Abolish Contract Practice.—Physicians of Cumberland met December 20, and adopted a resolution "to abolish all contract practice as applied to medical service of every sort in the city." Dr. Francis E. Harrington was chairman of the meeting, and Dr. John B. Littlefield, secretary.

Bequests.—By the wills of Mrs. Mary E. Burns and her daughter, Mrs. Ella B. Beaston, Eudowood Hospital for Consumptives, near Towson, will eventually receive a bequest of nearly $350,000. Other bequests provided are $10,000 to the Hospital for the Women of Maryland, $10,000 to the Church Home and Infirmary, $5,000 to the Baltimore Day Nursery, and $1,000 to Dr. Thomas C. Stellwagen, Jr., Philadelphia.

Personal.—Dr. John Sloan, organizer of the Board of Trade of Lonaconing, was given a banquet, December 20, prior to his departure to his new home in North Yakima, Wash.——Dr. William L. Smith has been appointed physician of the Baltimore county jail, and Dr. W. E. Ensor, physician of the county almshouse.——Dr. Arthur L. Wright has been elected pathologist at Spring Grove State Hospital for the Insane, vice Dr. Robert P. Winterode, resigned.

Baltimore

Near the Million.—The Johns Hopkins University fund has reached $950,000, leaving only $50,000 to be subscribed to complete the million necessary to complete the fund for the removal of the institution to its new site at Homewood.

Personal.—Dr. William J. Schmitz has been promoted to second assistant bacteriologist in the city health department. ——Dr. George L. Wilkins, city jail physician, was seriously injured and bruised, December 21, by being caught in an ascending elevator in the jail.

Donation to School.—Mrs. William Painter has given $20,000 to the Children's Hospital School to be used for the erection of buildings for the education and care of convalescent, crippled and invalid children. Other buildings will, it is contemplated, be erected in the future.

MICHIGAN

Personal.—Dr. Henry M. Joy of the Calumet and Hecla medical staff, has returned from Europe.——Dr. A. Verne Wenger, Grand Rapids, who has been ill in a hospital with septicemia, is convalescent and has resumed practice.——Dr. Homer I. Kedney, Marcellus, was painfully injured, December 15, by being thrown from his cutter.——Dr. George E. Moore, Ironwood, has been reelected physician of Gogebic County.—— Dr. William H. Marshall, Boyne City, has started for Europe. ——Dr. H. Allen Moyer, Charlotte, fractured his right arm and sprained his right wrist recently while cranking his automobile.

State Tuberculosis Society Meets.—The fourth annual meeting of the Michigan Society for the Prevention of Tuberculosis was held in Ann Arbor, December 10. The following officers were elected: president, Dr. Alfred S. Warthin, Ann Arbor; vice-presidents, Drs. Guy L. Kiefer, Detroit, and Edward F. Abrams, Dollar Bay; secretary, Miss Carroll Welton, Ann Arbor; treasurer, Dr. Henry J. Hartz, Detroit; and directors, Miss Ella Hubbard, Houghton; Drs. Charles Jennings and

Guy L. Kiefer, Detroit, and Mrs. M. W. Smith, Hastings (reelected), and Mrs. Lucy Toms, Lapeer, and Miss Carroll Welton, Ann Arbor.

MISSOURI

Elections.—At the annual meeting of the St. Joseph-Buchanan County Medical Society, held December 7, the following officers were elected: Dr. Samuel F. Kessler, president; Drs. John I. Byrne and James F. Owens, vice-presidents; Dr. Herbert Lee, secretary; Dr. John M. Bell, treasurer, all of St. Joseph, and Dr. Clarence O. Jefferies, Savannah, delegate to the state association, and Dr. Charles R. Woodson, St. Joseph, alternate.——Platte County Medical Association, at its meeting in Platte City, elected the following officers: Dr. Egbert R. Hull, Camden Point, president; Dr. John W. Shulz, Weston, vice-president; Dr. Albert S. J. Smith, Dearborn, secretary; Dr. Frank M. Shafer, Edgerton, treasurer; Dr. Joseph J. Carter, Weston, delegate to the state association, and Dr. James H. Winter, Parkville, censor.——At the annual meeting of the Grundy County Medical Society, held December 6, in Trenton, Dr. William H. Winningham was elected president; Dr. Edgar A. Duffy, vice-president; Dr. Samuel Sheldon, secretary; Dr. William D. Fulkerson, treasurer and censor, all of Trenton, and Dr. John M. Stone, Laredo, delegate to the state Medical Association.——Jackson County Medical Society, at its annual meeting in Kansas City, December 6, elected Dr. Jefferson Davis Griffith, president; Dr. James Q. Chambers, vice president; Dr. Edward L. Stewart, secretary; Dr. William F. Kuhn, treasurer, and Dr. Frederick T. Van Eman, censor.

St. Louis

Hospital Saturday and Sunday.—The donations on account of Hospital Saturday and Sunday have passed the $41,000 mark, and the managers expect that not less than $50,000 will be donated for the charities of the city.

Work Commenced on Hospital.—Ground has been broken for the new hospital to be erected by the Sisters of Mercy to form the clinical department of St. Louis University. The building will be five stories in height, will have 125 private rooms and 4 wards, and will cost $350,000.

The Cocain Crusade.—Following the report made to the police department that cocain was being sold very generally in the downtown district, the police on November 20 and 21, arrested seventeen individuals charged with selling or using cocain. One of the defendants, charged with peddling cocain without license, was discharged, December 1, on account of the case against him not being properly prepared. Meanwhile, cocain traffic is said to flourish openly. A reporter for a local paper purchased nine packages of cocain in the course of twenty-four hours.

NEW YORK

New Sanatoria.—The Tupper Lake Sanatorium Corporation has been given permission to establish a private sanatorium for the treatment of tuberculosis at Tupper Lake.——The supervisors of Saratoga County have decided to build a tuberculosis sanatorium for the county, and have appointed a committee of five to investigate sites, secure the consent of authorities, prepare plans and specifications and report back to the board.

Opposition to Hospital Overcome.—Approval has been given by the State Commissioner of Health, Dr. Porter, and Health Officer Dr. J. S. White, Moreau, to the application of the Metropolitan Life Insurance Company for the establishment at Mount McGregor, Saratoga County, of a hospital eight miles out of Saratoga for the treatment of its employees afflicted with tuberculosis. The plan was vigorously opposed by the residents of Saratoga Springs, who asserted that it would injure the village as a summer resort.

New York City

Oppenheimer Institute Not Approved.—The State Board of Charities at its last meeting refused to approve the certificate of incorporation of the Oppenheimer Institute, which claims to cure the drink habit. This action is part of a fight that is being made against the institute by the New York County Medical Society on the ground that the law provides that a corporation may not advertise to practice medicine unless it be a hospital corporation formed under the membership corporation law and have obtained a certificate of incorporation from the State Board of Charities. The case is still pending.

Koch Memorial.—At the New York Academy of Medicine meeting, December 15, the president, Dr. John A. Wyeth, gave a brief memorial address on the late Dr. Robert Koch, honorary fellow of the academy. Dr. S. Adolphus Knopf, who was a student under Dr. Koch, presented a portrait of Dr. Koch. In closing his remarks Dr. Knopf said "Let this portrait which shall henceforth grace the walls of our beloved academy, this likeness of a prince of science, a teacher of teachers, one of the greatest physicians of his time, remind present and future academicians of Koch's motto in life: 'Nunquam otiosus' (never be idle). Let it be to us an inspiration, an incentive, and a reminder of the fact that though man has done much, there is still more to do."

Alliance Between Hospital and Medical School.—Announcement has just been made of a gift of $1,500,000 to the Presbyterian Hospital, for the purpose of making possible an alliance between the hospital and the medical department of Columbia University. Edward S. Harkness gave part of the money himself and presented the remainder in behalf of a donor whose name he was not at liberty to mention. This alliance has been under discussion for some time and when it is finally consummated there will exist practically the same relation between the two institutions as now exists between the Johns Hopkins University and the Johns Hopkins Hospital. The fundamental principle of the alliance is that the university, in return for the privilege of making all nominations to the hospital staff, shall meet the expenses of all scientific and educational work associated with the hospital. It is for this purpose that the gift has been made. There are certain conditions imposed by the donor, some of which may be changed from time to time. One condition calls for the privilege of placing a memorial tablet in the new building of the hospital, which is soon to be erected, and it is rumored that this tablet will be in memory of Dr. Andrew McCosh. This is the first alliance of this kind between a medical college and a hospital in this city.

NORTH CAROLINA

Health Talks.—Dr. Watson S. Rankin, secretary of the State Board of Health, Raleigh, addressed the school teachers of Mecklenburg County at Charlotte, December 5, on "The Vital Problems of Public Health and the Teacher's Responsibility."

Society Meetings.—The first annual meeting of the Seventh District Medical Society, which includes the counties of Mecklenburg, Anson, Cabarrus, Lincoln, Union, Gaston, Stanly, Cleveland and Rutherford, was held in Charlotte, December 6. Dr. Andrew J. Crowell, Charlotte, acted as temporary president, and Dr. Robert H. Lafferty, Charlotte, as temporary secretary. The next meeting will be held in Gastonia.——Forsyth County Medical Association held its annual meeting in Winston-Salem, December 13, and elected the following officers: president, Dr. Aaron Y. Linville; vice-president, Dr. Everett A. Lockett; secretary, Dr. Eugene P. Gray, and delegate to the Medical Society of the State of South Carolina, Dr. Thomas W. Davis, all of Winston-Salem.

OHIO

Appropriation for Laboratory.—Dr. Bernhard F. C. Becker, health officer of Toledo, with the help of the Toledo Academy of Medicine and a federation of the Women's Clubs, has secured the approval of an appropriation of $1,000 for a bacteriological laboratory for the city.

Academy of Medicine Meets.—At the meeting of physicians of East Liverpool, Wellsville, Chester and Newell, held in East Liverpool, November 25, the Ohio Valley Academy of Medicine was organized. Dr. George P. Ikirt, East Liverpool, was elected temporary chairman. The academy proposed to follow the postgraduate course suggested by the American Medical Association.

PENNSYLVANIA

Personal.—Dr. Wilmer R. Ba [illegible] gistrar, was taken to the Harrisburg [illegible] uffering with appendicitis.——Dr. Pau [illegible] to the State Hospital, Warren, is suffering with septicemia, contracted in performing an autopsy.

Loving-Cup Presented.—Dr. Edward H. Small, Pittsburg, who has been compelled on account of illness to move to Saranac Lake, N. Y., sent his resignation to the Pittsburg Academy of Medicine, of which he was one of the first members and the founder of its library. The Academy of Medicine declined to accept the resignation and sent Dr. Small a message to that effect accompanied by a silver loving-cup in token of the affection and esteem in which he is held.

Bequest.—The will of the late Elizabeth W. Garrett, widow of the late Casper S. Garrett, the millionaire paper manufacturer, provides for a country home for poor children and deserving single women. Nearly $500,000 is bequeathed to relatives on condition that they withdraw all claim to 200 acres of farm lands and buildings thereon, situated near Newton Square, Delaware County. The institution is to be known as the "Garrett-Williamson Lodge," and will be run on principles similar to the country week associations.

Philadelphia

Research Laboratory for Stomach Hospital.—Plans for a research laboratory for the American Hospital for Diseases of the Stomach have been approved by the managers. The new building will be a two-story fireproof structure equipped with the latest appliances.

Wills Eye Hospital Appointments.—At a meeting of the board of city trusts on December 13, last year's officers of the Wills Eye Hospital were reelected. Dr. John A. Kenney was appointed resident surgeon and Drs. Luther C. Peter and Elmer E. Johnson were made clinical assistants.

Frankford Hospital Enlarged.—The Frankford Hospital formally opened the new Adele D. Schlechter Maternity, the Schlechter Home for Nurses and the Hunter Home for Nurses on the evening of December 16. Besides these additions, a wing to the Frankford Hospital building is in the course of erection.

New Anatomic Building.—The building of the former Pennsylvania Dental College, purchased some months ago and presented by Mr. Daniel Baugh to the Jefferson Medical College, is to be remodeled to serve as an anatomic laboratory. The cost of reconstruction will be about $100,000, also the gift of Mr. Baugh, and the building will be known as the Daniel Baugh Institute of Anatomy of Jefferson Medical College.

Small-Pox on Steamer.—When the North German Lloyd steamer *Chemnitz* was docked on December 17, the health officers sent five children with measles and one, supposed to be suffering with chicken-pox, to the Philadelphia Hospital. Later it developed that there was a case of small-pox among them, and the chief medical inspector sent three physicians to the government detention station to vaccinate every person held there for examination.

SOUTH CAROLINA

Eyeglass Peddlers Convicted.—D. Copeland and S. Frieburg, charged at [illegible] obtaining money under false pretenses, [illegible] medicine in the state without first having procured a license, are said to have been found guilty and sentenced to serve one year in the chain gang. The defendants are said to have assumed the names of reputable physicians of Atlanta and Spartanburg. They have appealed their case to the supreme court of the state.

State Board of Health Bulletin.—The South Carolina State Board of Health is issuing an interesting series of bulletins for free distribution throughout the state, the first of which was on "Small-Pox, Its Control Suppression and Prevention," the second on "The Mosquito, The House Fly (*Musca domestica*), The Typhoid Fly," the third on "Typhoid Fever and How to Prevent It," the fourth on "Diphtheria and Scarlet Fever, Their Restriction and Prevention," the fifth on "Clean Milk in the Home," the sixth on "Hookworm Disease," the seventh on "Anterior Poliomyelitis (Infantile Paralysis)," and the eighth on "Tuberculosis."

Medical Society Election.—At the annual meeting of the Columbia Medical Society, held December 12, the following officers were elected: president, Dr. Skottowe B. Fishburne; vice-president, Dr. Henry W. Rice; secretary-treasurer, Dr. Mary R. Baker, and delegates to the state association, Drs. Augustus B. Knowlton and Pinckney V. Mikell.——Greenville County Medical Society held its annual meeting, December 5, in Greenville, and elected the following officers: president, Dr. Anthony White, Mauldin; vice-president, Dr. W. B. Sparkman, Greenville; secretary, Dr. Charles O. Bates, Greenville, and treasurer, Dr. R. W. Bruce, Greenville.

TENNESSEE

New Infirmary.—A new infirmary is to be erected in Chattanooga by Drs. Edward T. and E. Dunbar Newell, to cost $50,000. The institution will contain thirty-two rooms and will be fully equipped.

Three Hospitals in One Building.—Drs. William G. Bogart, John S. B. Woolford and Raymond Wallace have each leased an entire floor in the new Highland Apartments, Chattanooga, and will operate independent private hospitals.

Boyd Memorial.—Work has begun on the memorial arch which is to be erected by the Boyd Memorial Association in memory of the late Dr. John M. Boyd, Knoxville. The arch is to be built of Tennessee marble and will stand at the front of the court house.

Election of Officers.—The annual meeting of the Maury County Medical Society was held in Columbia, December 9. Dr. Horace E. Thomas, Columbia, was elected president; Drs. Henry O. Anderson, Williamsport, and James G. Williamson, Jr., Columbia, vice-presidents, and Dr. Maximilian M. Cook, Santa Fé, secretary-treasurer (reelected).

VIRGINIA

New College Building.—The trustees of the University College of Medicine, Richmond, have awarded contracts for a new college building, to cost $135,000, to replace the one recently burned. The new building will be erected on the site of the old college, will be of granite ashlar, red brick and cement construction, three stories and basement in height. The building will be ready for occupancy in about a year.

Personal.—Dr. R. Lindsay Robertson has been elected city physician of Charlottesville, vice Dr. Roy K. Flannagan, resigned to accept the position as state health inspector.——Dr. Joseph S. DeJarnette, superintendent of the Western State Hospital, Staunton, is ill with typhoid fever.——Dr. William A. Swimley, Winchester, was thrown from a street car in Washington recently and severely injured.——Dr. Robert C. Randolph, Boyce, is ill with typhoid fever in Winchester Memorial Hospital.

Elections.—The Southside Virginia Medical Association held its thirty-first annual meeting in Suffolk, December 13 and 14. The following officers were elected: president, Dr. J. Bolling Jones, Petersburg; vice-presidents, Drs. Edward R. Hart, Suffolk; William T. Moore, Valentine's; and H. M. Musgrove, Capron, and secretary-treasurer, Dr. Emmett F. Reese, Courtland. The spring meeting of the association will be held in Norfolk.——At the annual meeting of the Richmond Academy of Medicine and Surgery, December 13, the following officers were elected: Dr. George Ross, president; Drs. Alfred L. Gray, John S. Horsley, and Alexander G. Brown, vice-presidents; Dr. Mark W. Peyser, secretary (elected for the seventeenth term); Dr. William A. Shepherd, treasurer; Dr. George P. LaRoque, librarian; and Dr. William S. Gordon, chairman of the judiciary committee.

GENERAL NEWS

Interurban Academy Meets.—The annual meeting and banquet of the Interurban Medical Academy, composed of physicians of Duluth, Minn., and Superior, Wis., was held in Superior, November 23. Dr. Louis T. Pare, Duluth, was elected president; Dr. Thomas J. O'Leary, Superior, vice-president; Dr. Olin W. Rowe, Duluth, secretary-treasurer, and Dr. Luther A. Potter, Superior, censor for three years.

Seaboard Physicians Hold Meeting.—The fifteenth annual session of the Seaboard Medical Association of Virginia and North Carolina was held in Kinston, N. C., December 6-8, under the presidency of Dr. William T. Parrott, Kinston. The following officers were elected: President, Dr. Clarence Porter Jones, Newport News, Va., and secretary, Dr. J. Rainey Parker, Goldsboro, N. C. Newport News was selected as the place for the next meeting.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Dec. 9, 1910.

The Responsibility of Opticians

In this country a good deal of prescribing of spectacles is done by opticians, and a diploma in sight-testing has been instituted by a society composed of these persons. The medical profession has always objected to prescribing by opticians on the grounds that even if they can measure errors of refraction they are quite incompetent to diagnose or treat diseases of the eye, while the patients for whom they prescribe spectacles may be suffering from grave disease. A case hinging on this point has been tried. A woman, aged 23, sued a "qualified optician" (one with the diploma mentioned) for negligence in supplying spectacles and in examining and testing her eyes. She was a student studying science for a London degree and had passed all her examinations except the final one. She consulted the defendant's firm for her sight in 1907, 1908 and 1909. Her eyes were examined and tested and she was given two sets of spectacles. Eventually she sought medical advice and it was found that she was suffering from conical cornea, which permanently prevented her from continuing reading, and she became nearly blind. She asserted that if she had received proper advice from the defendant she would have consulted an oculist in time. She first went to him in September, 1907, and was seen by his assistant, who tested her sight and according to her evidence used an ophthalmoscope. He said that her defective sight was due to astigmatism and that with his glasses her sight would be good and she might in time be able to dispense with them. In the spring of 1908, she went again and complained that print appeared blurred. Her eyes were again examined and the glasses were changed without advantage. In November, 1909, she consulted an oculist, who said that conical cornea must have existed since she first consulted the defendant, and that any one with any knowledge of the eyes would have detected this and forbidden her reading, and that her sight would probably have been preserved or, at any rate prolonged, but that now it was too late and she was on the verge of blindness. Evidence to this effect was given by the oculist in question, who also said that the glasses prescribed were wrong and quite useless. The optician was examined and stated that he prescribed for the plaintiff by means of test-types and did not use an ophthalmoscope but might have used a plain mirror. Medical evidence was given for the defense that conical cornea was hard to detect in its early stages. The judge, in summing up, pointed out that the defendant was not a professional man, and that, therefore, no standard of skill was applicable to him. People ordered glasses as they did telescopes, at their own risk. An optician was bound to exercise reasonable care, and if he found some disease should refer the patient to an oculist. He did not think it was an optician's duty to detect diseases of the eye. After a long discussion the jury failed to agree.

Radium for England

Mr. Alton, director of the English Radium Institute, has bought from the Austrian Ministry 1 gm. of radium for $75,000. This purchase was made on behalf of the well-known Jewish philanthropist, Sir Ernest Cassel, who will present it to the institute. According to the eminent scientist, Sir William Ramsay, a gram of radium is a fifth of the entire quantity in the world. In a previous letter (The Journal, Nov. 5, 1910, p. 1658) an important discovery of pitchblende in Cornwall mines, which promise to be an even better source of supply than the Austrian, was announced. It is evident that the Radium Institute, which will soon be opened, will be well supplied with the precious metal.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec. 2, 1910.

Reorganization of the Service of Military Sanitation

In one of my previous letters (The Journal, March 12, 1910, p. 885) I mentioned the insufficient number of military physicians. The minister of war has presented a bill to increase them by 217. A counter-project has been presented to increase the proportion of positions of superior grade as well as the whole number of physicians. The condition from which the army surgical corps has b [illegible] is shown by the increasing number of [illegible] for early retirement, as well as by [illegible] in the number of candidates for the special schools of Lyons and Val-de-Grâce. The acuteness of this crisis is shown by the fact that in 1909, seventy-two military physicians resigned and there were only fifty-seven nominations. This year a *concours* at Val-de-Grâce for fifty-five places of *stagiaire* physicians brought together only thirty-one candidates. Evidently, an increase in the number of military physicians will require to be supplemented by increased chance of advancement.

An Epidemic of Trachoma

The lay press has created some stir over an epidemic of trachoma which appears to have been raging for some time in some of the arrondissements of Paris, and which is attributed to the influx of Jews and Armenians from Syria, Egypt and other Asiatic countries. Some have even gone so far as to propose the expulsion of these immigrants. This harsh measure seems not only inhuman but unjustifiable, for the importance of the epidemic has been exaggerated and, moreover, trachoma is endemic in certain parts of France, especially in the South. It would be far more rational to give hygienic instruction to those who come into contact with immigrants subject to trachoma.

Masseurs and the Illegal Practice of Medicine

The case of a masseur accused of practicing medicine contrary to law was recently before the courts. The defendant pleaded that in case of disease he sent the patient to a physician, and confined himself to practicing Swedish medicine. The prosecutor, however, brought out the fact that the defendant called himself a "Swedish gymnastic physician" and that on his cards were printed the names of diseases which the defendant treated, not as a masseur, but as a physician who gives fixed hours of consultation. The defendant, moreover, admitted that to know what part ought to be massaged it was necessary to examine the patient; this implied a diagnosis and a line of treatment. A newspaper, moreover, related the marvelous cures which the defendant was said to have made on patients whom physicians had declared incurable. The court found him guilty of illegal practice of medicine and fined him $20 (100 francs).

International Agreement in Regard to Industrial Accidents

An agreement has been signed between France and Great Britain intended to assure to the citizens of each country the reciprocal benefit of the legislation in force in the two countries in regard to the payment of damages by industrial accidents. A similar agreement was concluded some years ago between France and Italy.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec. 1, 1910.

The Kaiser on Temperance

At the opening of a naval academy a few days ago, the emperor addressed the cadets and advised them to avoid the use of alcohol and to join the Good Templars. He said that the next war would demand healthy men and that victory would be on the side of that nation which showed the smallest consumption of alcohol. So at least the papers reported; whether it literally accords with what the emperor said, I doubt. At least it may be assumed that the Kaiser, who also sometimes on social occasions likes "a good drop" (*einen guten Tropfen*) himself, did not intend to advise general abstinence. Nevertheless the teetotalers will undoubtedly quote the Kaiser's speech to support their arguments.

Proposed Abolishing of Brothels in Baden

As a result of a petition of the Baden Women's Associations (*Frauenvereine*), the Baden national assembly (*Landtag*) has voted a resolution to close all the present houses of ill fame in the grand duchy and that no more new ones be established; that appropriate measures be taken by the government for combating prostitution and restricting it as far as possible, and especially for the suppression of street prostitution, and that all the efforts of societies and individuals to this end be sustained as far as possible. In the preparation for the discussion of the preliminary bill for the new criminal code and the proposed legislation by the imperial upper house (*Bundesrath*) for the regulation of prostitution, the government is asked to have the entire question of prostitution submitted to an expert commission, assisted by capable women. The commission shall especially investigate the questions: 1. Whether the present form of *réglementation* cannot be replaced by another form of supervision of prostitution which will not make it so difficult for the victim of prostitution to return to an honest life. 2. Whether measures following the model of the Danish law of March 16, 1906, are not to be recommended against the constantly increasing venereal diseases. The government is further asked to make provision in the next budget for the installation of female assistants to the police in the large cities. The question of the protection of waitresses in saloons is also one to be thoroughly investigated and it is to be determined what further measures of protection, especially for young persons, ought to be introduced into the imperial trade regulations. As the government is opposed to abolition of segregation, it is very questionable whether the resolution passed by the *Landtag* will have any actual results.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Dec. 24, 1910.

Woodson, Thomas D., lieut., December 1, granted thirty days' leave of absence.

Long, Charles J., D.S., December 19, ordered to proceed to Forts Constitution, N. H.; Williams, Me., and Ethan Allen, Vt., for temporary duty.

Scott, Harold O., D.S., December 19, ordered to proceed to Forts Totten, N. Y.; Monroe, Va.; Myer, Va., and Washington Barracks, D. C., for temporary duty.

Leeper, John F., M.R.C., December 16, granted thirty days' leave of absence about Jan. 1, 1911.

Cullen, Charles W., M.R.C., December 16, ordered to proceed from Fort D. A. Russell, Wyo., to Fort Duchesne, Utah, for temporary duty.

Foster, George B., Jr., lieut., December 16, ordered to Washington Barracks, D. C., for temporary duty.

McAndrew, P. H., major, December 16, left Fort Terry, N. Y., on ten days' leave of absence.

Tetrault, Charles A., M.R.C., December 17, reported for temporary duty at Fort Terry, N. Y.

Chambers, William H., D.S., December 19, left West Point, N. Y., on two months' leave of absence.

Thomason, Henry D., captain, December 20, granted thirty days' leave of absence.

Gunckel, George I., D.S., December 19, left Fort Oglethorpe, Ga., on thirty days' leave of absence.

Leslie, Samuel H., D.S., December 19, reported for temporary duty at Fort Riley, Kan.

Conner, Dillis S., M.R.C., December 20, resignation accepted, to take effect at date.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Dec. 21, 1910.

Pettus, W. J., asst. surg.-gen., directed to proceed to Baltimore and make inspection of the operations of the service at that port; granted five days' leave of absence from Dec. 27, 1910.

Carter, H. R., surgeon, directed to proceed to Evansville, Ind., and make inspection of the operations of the service at that port.

Lumsden, L. L., P. A. surgeon, directed to proceed to Des Moines, Iowa, and confer with the secretary of the state board of health relative to an outbreak of typhoid fever.

McLaughlin, A. J., P. A. surgeon, directed to proceed to Buffalo, N. Y., via Albany, N. Y., on special temporary duty; granted five days' leave of absence en route.

Brooks, S. P., A. A. surgeon, leave of absence granted for seven days from Dec. 12, 1910, amended to read nineteen days from Dec. 13, 1919.

Cleaves, F. H., A. A. surgeon, granted six days' leave of absence from Dec. 24, 1910, under paragraph 210, Service Regulations.

Hart, G. G., A. A. surgeon, granted eleven days' leave of absence from Dec. 20, 1910.

Hume, Lea, A. A. surgeon, granted ten days' leave of absence from Dec. 13, 1910.

Tappan, J. W., A. A. surgeon, granted ten days' leave of absence from Dec. 17, 1910.

Limits to the Advance of Science.—In a study of American men of science, J. McKeen Cattell (*Science*, Nov. 4, 1910) says that a man of genius is likely to do his best work at an early age and to receive prompt recognition. "Kelvin was appointed full professor at Glasgow at 22, Thomson at Cambridge at 26, Rutherford at McGill at 27. Men of science of this age and rank simply do not exist in America at the present time; . . . the number of scientific men of standing is only about one-half so large as the increase in the population of the country. . . . Racial senescence, the lack of emotional stimuli, and the accumulations of knowledge will probably set limits to the further advance of science. In the presence of racial senescence we should be entirely helpless, but it is possible that there is no such thing. Twenty years ago the Chinese were called a senile race, but such a statement could not be justified to-day. In a way our stock is as young as any, and the germ plasm may increase as much in complexity as it has since the ameba. Still a highly specialized organism is likely to become unplastic and extinct, and apart from physical exhaustion of the stock there is likely to be a social senescence. This is closely related to the lack of emotional stimuli. Great men and great achievements are likely to be associated with national excitement, with wars, . . . and the like. Such stirring events will probably disappear from the world civilization of the future, and it may be impossible to devise artificial stimuli adequate to arouse men from a safe and stupid existence. But exactly because within a century the great achievements of science may belong to the past, where the great creations in poetry, art and religion may perhaps now only be found, it is our business to do the best we can to assure the race of an adequate endowment."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SIGNIFICANCE OF LARGE VACCINATION SCARS

To the Editor:—1. Of what value, as evidence of successful vaccination, is a large and distinct scar?

2. Is it probable that most of the unfavorable conditions and large scars following vaccination are due to infections other than the vaccine virus? EUSTACE LONG, Madison, Fla.

ANSWER.—1. The size of the scar is of itself no positive evidence of successful vaccination. The size may be due to the severity of associated infection. What is characteristic of successful vaccination is the minute depressions in the scar.

2. It is probable that most of the unfavorable conditions following vaccination are due to infections of a mixed character, but it seems to be true that an active though pure vaccine virus may sometimes produce extensive inflammation and large scars.

DIFFERENCE BETWEEN GERMICIDE AND ANTISEPTIC

To the Editor:—Please state briefly the difference between a germicide and an antiseptic. In what way does a non-germicidal antiseptic relieve infections such as are met in out-patient work? W. I. CLARK, Worcester, Mass.

ANSWER.—A germicide is a substance or agent which destroys microorganisms so that they will not grow when placed in appropriate culture media. An antiseptic is a substance which hinders or prevents the growth of microorganisms but does not necessarily destroy their vitality. Organisms which have been treated with non-germicidal antiseptics will grow in appropriate culture media if the antiseptic is thoroughly removed Non-germicidal antiseptics may stimulate the tissues, so as to render them more active in resisting infection.

HARRINGTON'S SOLUTION FOR HAND ASEPSIS

To the Editor:—Can you give me the formula for making Harrington's antiseptic solution? P. F. DODSON, Wilber, Neb.

ANSWER.—Harrington's solution consists of commercial alcohol (94 per cent.), 640 c.c.; hydrochloric acid, 60 c.c.; water, 300 c.c.; corrosive sublimate, 0.8 gm. It is intended for hand disinfection. The hands and arms should first be thoroughly washed with sterile soap and hot water and then bathed in the solution for half a minute or longer.

Book Notice

SYMPTOMATIC AND REGIONAL THERAPEUTICS. By George Howard Hoxie, M.D., Professor of Internal Medicine and Dean of the Clinical Department in the School of Medicine of the University of Kansas. Cloth. Price, $4. Pp. 499, with 58 illustrations. New York: D. Appleton & Co., 1910.

In the preface the author says that this book contains the material recommended by the Committee on Curriculum of the American Medical Association and by a similar committee of the Association of American Medical Colleges for the college course in therapeutics. It is divided into three parts: the first is devoted to symptomatic therapeutics; the second to regional therapeutics or therapeutics of lesions or diseases; and the third to notes on remedies. The first part is the most satisfactory and the last the least so.

The individual chapters are not so carefully planned as they might have been. For instance, in the one devoted to pain, local treatment is first described, then drug treatment; and following that section is one devoted to "other drug treatment." But under the last head a page is devoted to local treatment again. The chapter devoted to the nature of fever is not explicit enough, and the methods of giving baths in typhoid and other fevers are not described with sufficient fulness. Certainly a student could not learn from the description precisely how, when, or for how long a time the bath can be best given. Nor are these facts brought out further on in the book when typhoid is specifically discussed. The description of asthma occupies only part of a page, and for a work devoted to treatment the discussion of the subject is unsatisfactory.

For the undergraduate, for whom the book is said to be intended, it is not detailed enough. Many subjects are so treated that one feels pleased, but not quite satisfied, with what one has read. In particular, too little is said of just how individual drugs and remedial procedures do good when prescribed for symptoms or diseases; and not enough pains are taken to point out exactly when they should be used in a given disease, for it is rare that any one remedy is useful or best throughout the course of a disease. The notes on remedies are most unsatisfactory, for they do not discuss fully either the mode of action or the pharmacology; and these are subjects on which the student should be well informed. Drugs are included which are of little or no value, while insufficient space is given to the more important ones.

However, in spite of the defects to which we call attention, the book on the whole is commendable; it will be useful to practitioners who desire to refresh their memories of this subject and to bring their practical knowledge up to date.

1 Rhinolaryngology and Its Relation to General Medicine. H. Arrowsmith, Brooklyn.
2 *Etiology of Poliomyelitis. F. Proescher, Pittsburg.
3 Endemic Poliomyelitis. W. S. Bryant, New York.
4 Congenital Hypertrophic Stenosis of the Pylorus. R. Harrison, Philadelphia.
5 Mixed Cell Sarcoma of the Pituitary Body. M. O'Malley, Washington, D. C.
6 Froehlich's Syndrome in Cases of Pituitary Tumor. R. Ottenberg, New York.
7 *Spontaneous Appearance of Indigo Blue in the Urine. A. L. Benedict, Buffalo.
8 Insufficient Pylorus. B. Frankel, New York.
9 Magic and Medicine. J. Knott, Dublin, Ireland.

2. Etiology of Poliomyelitis.—A peculiar kind of micro-organism was found by Proescher in a fatal case of poliomyelitis, with the usual well-known lesions of the spinal cord. Microscopically, perivascular infiltrations, hemorrhages, and degenerations of the ganglionic cells were found throughout the spinal cord. To confirm the diagnosis, a monkey was inoculated into the right paracentral convolution, and into the peritoneal cavity, with an emulsion made from various parts of the spinal cord and brain. The animal recovered from the operation and an hour later appeared in a normal condition. No change occurred during the next six days, but on the seventh day a marked ptosis of the left eye developed so that the lifting up of the eyelid became difficult. The temperature ranged from 103.2 F. (normal temperature) to 105.4 F. In other respects the animal seemed well and had normal appetite. The ptosis lasted for three days, when it disappeared, and was followed on the morning of the twelfth day after inoculation by a complete paralysis of the left leg. The movements of the right leg and both arms were normal and no other clinical signs were noted. Temperature, 102.3 F. Daily examination of the blood showed a relative lymphocytosis. On the sixteenth day after inoculation the animal was killed, and the postmortem showed no macroscopic changes in the brain or cord, except a slight hyperemia and edema of the lumbar section. Internal organs were apparently normal. The microscopic examination of the cord and brain, gave the same lesions as found in the nervous system of a child. Smears were made from the fresh cord, hardened in bichloric alcohol, subjected to the action of dilute Lugol's solution and of sodium thiosulphate and stained by Mann's method. Peculiar cell inclusions, resembling Negri bodies, and also parasitic formations similar to protozoic bodies, were found. In regard to the true nature of parasitic inclusions, no explanation at present seems available.

7. Indigo Blue in Urine.—After the administration of benzoic acid in a proprietary mixture, the urine was of a peculiar brownish-green color. On adding chloroform, the blue was extracted, and, from the correspondence with previous and subsequent indican tests, the difference in tint from anilin cases and the exclusion of adventitious and dietetic causes of coloration, was regarded as indigo. The impure brownish-green color of the urine before shaking with chloroform was regarded as the mixture of indigo with the ordinary yellowish-brown pigment, the urine containing a uratic deposit. It is suggested by Benedict that the benzoic acid may have acted as an oxidizing agent both in this case and in various others in which spontaneous passage of blue urine has been noted.

18 Extraperitoneal Cesarean Section. J. L. Huntington, Boston.

16. Tuberculosis Problem as Applied to Children.—As an outline for future work of anti-tuberculosis societies, Hawes suggests the following: 1. Every effort should be made to get the state and local authorities to provide adequate facilities for the care of children with pulmonary tuberculosis. One effective way of doing this is to make application for the admission of all such cases to the state sanatoria. The strongest argument which the board of trustees of the state sanatoria can use before the legislature is a long list of applications from children for whom there is no place, nor for whom, with the present appropriation, can a place be provided. 2. Earnest and intelligent cooperation with the local school board to provide an outdoor school or fresh-air room for pre-tuberculous children; if such a school or room is established, the attention of the city legislature and board of health should be called to the good which it does. 3. It should be insisted on that the terms of the 1908 act, that "tuberculosis and its prevention shall be taught in our public schools," etc., be complied with. This can best be done by means of tuberculosis exhibits prepared along the line of those now loaned by the state, placed in all the public schools, and demonstrated wherever possible by physicians, nurses or social workers.

13 *Ideal Operation for Fistula in Ano. S. C. Evans.
14 Operative Treatment of Hydrocele. C. Hudson.
15 Treatment of Stricture of the Urethra and of Fistulæ. P. C. Gabbett.

4. Sterilization of Skin by Iodin.—Hamilton has used an alcoholic solution of iodin in water in over seventy cases with good results. A few minutes before the patient is brought to the table the field of operation is thoroughly painted over with the solution and allowed to dry. Immediately anesthesia is complete a second coating is given and then the operation is commenced. On the completion of the operation the line of sutures is lightly painted over with the same solution.

12. **Treatment of Senile Enlargement of Prostate.**—Smith makes a crescentic wound from tuber-ischium to tuber-ischium with its convexity about an inch in front of the anus. He separates the anus and lower part of the rectum from the distal or penile half of the prostate. With a median staff in the bladder, take the staff in one hand and turn it so that its groove will be postero-lateral, into which pass the knife at the apex of the prostate and on into the bladder, making a lateral incision. Then turn the staff to look postero-lateral in the opposite direction and make a corresponding cut in the other side: so that the v-shaped tongue left by the junction of these two cuts will have in it the median septum and the termination of the seminal ducts which would thus be out of the way and out of danger. Then pass a finger into the capsule of the prostate in one side and enucleate it by working around it from the lateral aspect and finishing by enucleating that lateral half from the urethra and posterior septum. Repeat the process with the other lateral half. If there is a median lobe deal with it directly. By this method one need not injure the anterior part of the urethra or the seminal ducts. All bleeding points can be caught with forceps and twisted in proper surgical fashion, as they are visible. Proper drainage is secured, and the wounds heal up as quickly as in an ordinary lateral lithotomy and the results are good.

13. **Operation for Fistula in Ano.**—The patient is placed in the lithotomy position with the buttocks well over the end of the table. The sphincter is dilated in the usual way and the rectum douched out with sterile normal saline solution or weak biniodid. Beginning at any convenient external opening the main fistula and all lateral diverticula beyond the limits of the sphincter are laid freely open. Any prominent vessels are now picked up, the surface dried and attention directed to the anal end of the gaping wound. This corner must be explored with the greatest pains and with the greatest gentleness, with probes of diminishing size, until the rectal opening, or, when none exists, the summit of the fistula is discovered. Great care should be exercised at this stage lest the probe, infected from the main tract, be thrust into healthy tissues. The probe is followed by a director and the fistula laid open in such a manner as to divide the sphincter in a radial direction. The incision involves the mucous membrane of the rectum up to the internal opening or, where no such opening exists, to the level of the summit of the tract. A few bleeding points now need picking up.

The next step is to remove all diseased tissue. With a sharp scalpel (the knife must be sharp) a v-shaped piece is cut out of the bottom of the gutters left by splitting open the fistula and its ramifications in such a manner as to remove all granulation tissue. The section leaves a clean white shiny surface dotted with minute bleeding points. Any undiscovered diverticula are indicated by small dark patches of granulation tissue. These are similarly laid open and their lining excised. As soon as the granulation tissue lining the main tract is cut away lateral ramifications at once become evident. Attention is now turned to the skin and all thin, discolored and diseased overhanging portions are trimmed away with scissors or knife. The next step is to close the somewhat irregular and usually extensive wound with sutures. The material used is silkworm gut. The left forefinger is introduced into the rectum. The needle is entered at the anal margin on one side of the wound, is made to transverse the sphincter and run just beneath the mucous membrane of the rectum, till the summit of the wound is passed. The instrument is then grasped in the full of the hand and its direction forcibly altered in such a manner as to cause the point to travel round the apex of the wound and along beneath the mucous membrane of the rectum till it emerges at the anal margin on the opposite side. A series of stitches are introduced in this way. The first three are placed close together so as to bring the tissues in the sphincter region into accurate opposition. The remainder need not be quite so close, but great care must be taken to bring the sides of the entire wound into continuous contact. There must be no cavities where blood can collect. All the stitches are introduced before being tied. A double twist is preferable to a knot especially in the neighborhood of the anus, as there is always, when the time comes for removing the stiches, considerable difficulty in getting the point of a pair of scissors under the loop; the proceeding, moreover, is very painful. The ends of all sutures are left long to avoid the irritation of sharp wiry points, are tied up in one or more convenient bundles, and are wrapped up in iodoform gauze. A morphin and iodoform suppository is introduced into the rectum, the wound dusted freely with iodoform and boric acid and dressed with a pad of wool and a T-bandage. The patient's knees should be fastened together and his bowels kept confined with small doses of opium for four days. The results of the operation in Evan's experience are excellent—six failures out of 107 cases.

21. **Arteriosclerosis and Intestinal Poisons.**—Metchnikoff has continued his research on the poisons generated by the ordinary bacteria in the intestines, and believes that his experiments have now established beyond question that small doses of paracresol and indol, acting on the organism over a longer or shorter period, are capable of inducing chronic lesions of the nature of sclerosis. Such lesions are the very ones that are most frequently encountered in senility. His latest experimental and chemical research further demonstrates, he states, that the phenols and indol found in the stool and urine are not the excreta of our tissues, but are the products of the permanent microbian flora. It is not unreasonable to assume, he declares, that the digestive tract can constantly harbor an injurious flora, the source of chronic poisoning leading to arteriosclerosis; helminths are so frequent among certain primitive peoples that they may almost be regarded as the normal "physiologic" fauna, and yet they are liable at any moment to entail more or less serious disturbances. Mathis and Leger announced last year that they found helminths in every native examined in Indo-China. It is established now beyond question, he continues, that the *Bacillus perfringens* and the colon bacillus produce poisons which can be absorbed by the normal walls of the intestines and are capable of inducing serious lesions in vital organs, arteries, kidneys, liver, etc. He then discusses how to prevent this injurious action from the poisons thus engendered in the intestines. These same lesions occur in the horse and rabbit, which eat no meat; consequently, a meat diet cannot be the main cause, and experiences are showing that with a mixed diet there is really less production of these poisons. On the other hand, it seems to be possible to check the production of indol by these bacilli by fighting them with certain other bacilli, especially lactic-acid bacteria. The simultaneous presence of Bulgarian lactic-acid bacilli in a culture medium with the colon bacilli seems to render it impossible for the latter to attack the nitrogenous elements in the medium, and hence there is no production of substances of the aromatic series. Metchnikoff reiterates that it is on this principle of letting

Greek fight Greek that we may hope to find the solution of the problem of the suppression of the poisons which are responsible for the development of the sclerosis in our organs, and consequently of their premature wearing-out. (Metchnikoff's previous work in this line was reviewed to date in The Journal, March 19, 1910, page 970.)

29. **Treatment of Dangerous Gastric Hemorrhage.**—Kraft refers to severe hemorrhage from gastric ulcer, and cites statistics to show that this occurs in from 1.1 to 11.6 per cent. of all cases of gastric ulcer, while minute hemorrhage is encountered in about 75 per cent. The rarity of operative interference is due to the unsatisfactory technic hitherto, the outcome seldom answering anticipations, Kraft states, but, he continues, all this has been changed by Rovsing's method of direct diaphanoscopy and gastroscopy, the light introduced through a minute incision in the stomach wall. This has made the surgeon the master of the situation and has revolutionized the prognosis. (The technic was described in The Journal, Aug. 22, 1908, page 713.) Kraft has applied it in five cases; all the patients were cured at once, with the exception of one who was fatally injured by accidental short-circuiting of the electric current before the technic had been fully mastered. The diaphanoscopy permits exact knowledge of the source of the hemorrhage, and it is then readily obliterated by running a suture thread around it. The patients were prepared with saline infusion (1,000 c.c.) an hour before the operation; camphor and strophanthin were never given, as he thinks they render more of the anesthetic necessary. An injection of 200 c.c. of a 5 per cent. gelatin solution was made in a few cases, but no benefit from it could be detected. Immediately before the operation the stomach was cleaned out as completely as possible. If this has to be done during the operation it increases the operative risks. He has never found that lavage of the stomach increased the bleeding.

30. **Stab Wounds of the Diaphragm.**—Magula reports his experiences with operative treatment in sixty-one cases of stab wounds of the diaphragm at St. Petersburg. He has been able to find only 129 similar cases on record. Only twenty-five of his cases were without concomitant injury of other internal organs. The wound in the diaphragm was not diagnosed in 41 per cent. of the cases; in 9.7 per cent. the stab had been received in the fourth and fifth interspace. The danger of diaphragmatic hernia is so great as also the possibility of unsuspected injury of other organs that expectant treatment is contra-indicated. In case it proves impossible to suture the wound in the diaphragm, the lips of the wound may be sutured to the costal pleura as Frey has suggested. This prevents hernia and also danger of secondary infection of the pleural cavity.

31. **Stretching the Passage Through the Enlarged Prostate.**—Bayer has been advocating for some time instrumental dilatation of the prostatic portion of the urethra for difficulty in urination from chronic non-malignant enlargement of the prostate. The measure is particularly adapted for debilitated elderly patients, as it is so simple and harmless, and he reports complete success with it in five out of eleven cases and material improvement in two other cases. Only one of the patients has required prostatectomy since, after a period of transient improvement. The outcome in the other cases is not known, except that one patient has died from other causes. He uses a curving instrument like a lithotrite, except that one branch is made hollow to permit irrigation through it. The other branch fits over the first and by turning a thumbscrew the curving tip of the second branch slides along on the first branch, the curving tips thus separating, although remaining parallel. The separating branch exerts pressure toward the rectum, stretching the prostatic urethra in this direction. After the part has been stretched, he closes the instrument and flushes the region through it with *iodoform-glycerin* to aid in healing any slight lesions that may result from the dilatation. He has applied the instrument also in three quite recent cases. The dilatation may be repeated after a few weeks or months, if necessary.

34. **Restoration of the Nose.**—Wolkowitsch reports a number of rhinoplastic operations; in two of them he made the new nose out of the patient's fourth finger, as he describes in detail. The first case dates from 1896. His experience, he thinks, encourages further work in this line, as also with the Italian method of rhinoplasty which was applied in the other cases.

36. **Hernia in the Anterior Abdominal Wall.**—Denk urges operative treatment as early as possible, as the hernia is liable to increase with delay and with it the danger of recurrence. A plastic operation is the only reliable technic and catgut should be used for ligatures, as *primary* healing is indispensable. These conclusions are based on 135 operative cases at von Eiselsberg's clinic at Vienna, 1901-1910. In thirty other cases of the kind an operation was contra-indicated or refused. The technic preferred is described in detail and illustrated; the outcome was a permanent cure in 76.8 per cent. in the ninety-five cases followed to date, which he compares with the outcome in fourteen other clinics. There had been stitch-hole abscess in half of the twenty-two cases with recurrence, and drainage had been necessary in most of the other recurring cases.

37. **Treatment of Recent Fracture of Long Bones.**—Among the measures advocated by von Frisch is one to be applied when apparently unconquerable contraction of the muscles prevents apposition of the stumps after a transverse fracture. He shows by illustrations that if the lapping stumps are bent outward, at an angle of about 125 degrees, the contracting muscle on their inner side becomes slackened. It is then a simple matter to manipulate into apposition the inner edge of the two stumps thus meeting at the above angle of about 125 degrees. Then by pulling on the farther ends of the bones to bring the whole into a straight line, the inner edge of the stumps in apposition serves as a lever which brings the rest of the stump into apposition in spite of the opposition of the muscle. The very inequalities of the cleft ends of the stumps make them grip each other with a firmer hold, and the contraction of the muscle then serves to hold them immovably in contact. It is in this class of cases that extension is almost certain to fail, while the simple maneuver described rights conditions at one stroke and very little callus production follows. The manipulation is done after a few whiffs of ether—primary ether anesthesia—or in general anesthesia. The arm is placed in supination and then the hand is drawn toward the side to which the distal fragment projects, dorsal or ventral, while the surgeon's fingers manipulate the stump ends in the angle thus formed, pushing them into correct apposition. If the reduction is correctly done, the arm can be rotated afterward without danger of displacing the stumps again.

38. **Treatment of Fracture.**—Clairmont has found it possible to reduce certain fractures by introducing a retractor through a small incision and pulling the dislocated stumps into correct apposition with the instrument. In a case described, the fracture of the forearm was 13 days old and this little operation, after failure of bloodless reduction, answered the purpose admirably, as also in a case of fracture of the leg.

Medical Economics

West Virginia Adopts Medical Defense

At the annual meeting of the West Virginia State Medical Association, Dr W W Golden, chairman of the Committee on Medical Defense, presented a report, reviewing the history of cooperative medical defense and recommending changes in the by-laws to make it operative in West Virginia

After stating that it was the conviction of the committee that, in time medical defense would become a permanent feature of every state medical organization, the advantages of cooperative medical defense were outlined The committee held that any physician was liable to become the defendant in a suit for alleged malpractice at any time, the general practitioner being just as liable as the specialist, and the physician at the cross roads as the city doctor It consequently behooves all to take precautionary measures In most malpractice suits the trouble originates with some misguided and jealous fellow practitioner Consequently, the ideal prophylaxis is to be found in a more effective dissemination of the principles for which the medical organization stands Liability companies furnish protection to physicians at a very handsome premium, binding themselves to pay the amount of judgment up to a certain sum, as well as the expenses of the suit As most of the suits brought are for blackmail or for the purpose of offsetting the physician's bills, verdicts are not often found against physicians The committee regards the rate charged by liability companies as needlessly high, and states that members of the Wisconsin State Medical Society, for instance, get practically as good protection for $1 per year as that for which liability companies doing business in the state charge $15 The adoption of medical defense by the state society has invariably been followed by a marked diminution in the number of malpractice suits, not so much through the effect on the lawyer and the prospective plaintiff as on the "medical culprit" who is instigating the prosecution and whose sole object is persecution Again, should the policy holder be so unfortunate as to have more than one law suit brought against him in a short period, the liability company may take advantage of its right to cancel his policy The committee points out, however, that there is nothing in the adoption of medical defense by the state society to prevent those physicians who so desire from carrying personal liability policies in addition

The chief advantage of cooperative defense is that it enables all of the members of the state society to unite in securing the services of a competent attorney, who having all of the business of the state society, can afford to devote enough time to this subject to become proficient in it Those who have had experience with malpractice suits know that even the best lawyers are but little informed on the subject As has been frequently pointed out, the law of malpractice is almost entirely a law of court decisions rather than of statutory enactments An attorney, no matter how able, is at a disadvantage in defending a suit if he is not thoroughly familiar with the precedents and decisions on this subject This is particularly true of prominent and busy lawyers, as the demands on their time make it impossible for them to become thoroughly familiar with the law in the case The most important feature of cooperative medical defense by the state society is that such a provision makes it possible to retain a competent attorney who by constant application can in a short time become thoroughly familiar with the law It is not expected that one attorney would personally try all of the suits, but his advice and assistance to local attorneys would be of the greatest value As the committee well says, "this feature alone makes the adoption of a plan for medical defense highly desirable and the amount of $1 per year is certainly a small sum to pay for such a benefit"

The report discussed the value of this feature in attracting and holding members, and presented the necessary amendments to the by laws They provide for a committee on medical defense, composed of the members of the state council and three members especially elected for this purpose, the three members to constitute the executive committee. The executive committee is to select an attorney to look after the interests of the members of the state association One dollar per year is assessed against each member to defray the expenses of the committee on medical defense. No suits are to be defended based on acts committed prior to Jan 1, 1911, or prior to the date of qualification of the physician as a member of the association Only members in good standing are entitled to the privileges of medical defense.

The adoption of this feature by the West Virginia State Medical Association will greatly enhance the value of membership and will be productive of much good in that state, as it has in others

Slovenly and Shotgun Prescribing

A physician sends us the following letter as a contribution to the subject of the need of more careful prescription writing·

"A druggist showed me a prescription by one of the most prominent physicians in a neighboring city who long held a professorship in a leading medical school After turning the prescription in such a manner as to hide the writer's name, he permitted me to copy it, and I here reproduce it, preserving spelling and capitalization

℞	Terpin hydrate	gr xxx
	Quinia Sulphat	gr xx
	Heroin —	gr iss
	Pulv Nucis vomicae	gr vi
	Guaiacol Carb	gr xlv
	Ammoniae Muriat	ʒi
	Protonuclein	ʒi

M Fiat capsules No XX Sig One after meals

"Questions Why begin hydrate with a lower case letter, muriate with a capital? Presumably the dash after Heroin was to fill the line, or, did he wish the sulphate? Why Quinia, but Ammoniæ? Even granting that protonuclein has a remedial action when given separately, would it have any influence in such a combination? (The manufacturer's representative informed me that it was doubtful) Why Ammoniæ Muriat, instead of Ammonii Chloridi?

"I fully realize that it is easy to criticize, and that my own prescriptions are far from perfect, but it seems that such Gatling gun examples of polypharmacy, coming from leaders in the profession at this time, demonstrate the absolute necessity for more attention to this subject of prescription writing, in the journals and medical societies."

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

THE CHEMICAL PROPERTIES OF SALVARSAN ("606")

W. A. Puckner and W. S. Hilpert

At the request of the Council's referee for Salvarsan ("606"), its examination was taken up in the Association laboratory. Inasmuch as the statements in articles regarding the chemistry of this new remedy have been somewhat vague, it is deemed of interest to record the following experiments:

The specimen of Salvarsan was contained in a sealed glass tube said to contain 0.6 gm. of the product. To determine its content the tube was weighed, the contents transferred to a beaker, the tube washed out with water, dried and weighed. It was found that the contents of the tube amounted to 0.6510 gm. When the tube was opened a marked wood-spirit-like odor became apparent, probably due to the vapor with which the tube was filled as a means of preventing the decomposition of Salvarsan by air. The powder, which was light yellow in color, when treated with water became a soft, transparent, gelatin-like mass which dissolved to form a clear yellow solution. This solution was made up to 100 c.c. and portions used for the following tests:

TESTS

The solution was distinctly acid to litmus. When sodium hydroxid solution was added gradually, a precipitate appeared, which on further addition of alkali redissolved. The reaction which takes place apparently consists in the liberation of the water insoluble free base; thus, $\mathrm{HCl.NH_2.OH.C_6H_3.As{:}As.C_6H_3.OH.NH_2.HCl + 2NaOH \text{—>} NH_2.OH.C_6H_3.As{:}As.C_6H_3.OH.NH_2 + 2NaCl + 2H_2O}$, the phenolic hydroxyl of which then reacts with the alkali to form the water soluble sodium salt (the phenolate of the base) thus: $\mathrm{NH_2.OH.C_6H_3.As{:}As.C_6H_3.OH.NH_2 + 2NaOH \text{—>} NH_2.ONa.C_6H_3.As{:}As.C_6H_3.ONa.NH_2 + 2H_2O}$. When to the aqueous solution of Salvarsan a solution of sodium carbonate was added, a precipitate appeared, which did not dissolve when further quantities of the alkali carbonate were added.

The solution was not affected when treated respectively with diluted hydrochloric, diluted nitric and diluted sulphuric acids. When the aqueous solution was treated with strong nitric acid a yellowish-white precipitate was produced which redissolved when more acid was added, yielding finally a dark red solution. When the solution was treated with strong sulphuric acid a yellowish-white precipitate was formed which dissolved when more acid was added yielding a solution which at first was almost colorless, then became brown and finally black, apparently through carbonization.

When the solution was treated with a little ferric chlorid solution, a violet coloration, such as is given by many other phenols, was produced, which, on standing became dark red; finally the liquid became turbid. When the solution of Salvarsan was treated with dilute nitric acid and then silver nitrate solution added, a yellow precipitate was produced which rapidly darkened and soon became black. When the Salvarsan solution was treated with an alkaline solution of potassium permanganate and warmed, the permanganate was reduced and an odor of ammonia developed.

When the solution was treated gradually with a tenth-normal solution of iodin, the iodin was reduced as shown by disappearance of the iodin color and it was noted that at the same time the color of the Salvarsan solution became less pronounced. The gradual addition of iodin solution being continued, a colorless liquid finally was obtained. This reaction appears to be perfectly definite and in several experiments for 0.0651 gm. substance 10.5 c.c. tenth-normal iodin was required—this regardless of the dilution.

THE ARSENIC CONTENT

The arsenic content of Salvarsan was determined by treating 10 c.c. of the solution contained in a Kjeldahl flask with 25 c.c. of strong sulphuric acid and digesting this mixture until colorless. The colorless solution so obtained was diluted, neutralized with sodium hydroxid, an excess of sodium bicarbonate added and the arsenic content determined by titration with tenth-normal iodin, a method substantially the same as that used in the examination of atoxyl by W. A. Puckner and A. H. Clark (THE JOURNAL, A. M. A., Sept. 21, 1907, p. 1041).

Ten c.c. of Salvarsan solution containing 0.0651 gm. substance required (*a*) 5.67 c.c., (*b*) 5.71 c.c. or an average of 5.69 c.c. tenth-normal iodin solution, equivalent to 0.0211 gm. arsenic; calculating this on the basis of the weighed contents of the tube it indicates that the product contains 32.41 per cent. of arsenic. As the contents of the tube weighed 0.6510 gm. although the label claimed a content of 0.6 gm. it seemed probable that the excess weight was due to hygroscopic water or possibly to vapors of the substance used to replace the air in the tube.

Calculating the arsenic content on the assumption that the tube contained 0.6 gm. real Salvarsan, 35.16 per cent. of arsenic was indicated. As but a single tube of the material was at our disposal, no extended experiments regarding the arsenic content could be undertaken at this time. In view of this and in view of the difficulty of putting up an exact quantity of a material so unstable as this product, our examination must be taken as a confirmation of the chemical claims made for the product.

THE PRODUCT AND ITS BEHAVIOR

In order that physicians who use this substance may handle it more intelligently the following condensed description of its behavior is given: Salvarsan is an arsenic compound containing that metal in a low state of oxidation and the product is, therefore, a powerful reducing agent and is decomposed by bodies which are oxidizers, including air. The amine groups of the body give it the character of a weak base enabling it to form salts such as the chlorid, the salt that constitutes Salvarsan. Being a weak base, its hydrochlorid, when dissolved in water, is largely decomposed by the latter (hydrolysed) and hence gives a solution having an acid reaction. A solution of Salvarsan is, therefore, acid and will remain so until for every molecule of Salvarsan there have been added two molecules of sodium hydroxid or a similar monovalent base.

Salvarsan also contains two phenol (hydroxyl) groups and in agreement with phenols in general it forms compounds with strong bases (phenolates). When, therefore, the free base from Salvarsan has been precipitated by addition of an alkali and further alkali is added, a clear solution of the sodium salt will result when two further molecules of sodium hydroxid or a similar monovalent base have been added. It is the free insoluble base that is injected subcutaneously and intramuscularly in the form of a suspension and it is the alkaline water-soluble sodium salt which is injected intravenously in the form of a solution.

Marriages

ARTHUR CHARLES STOKES, M.D., to Miss Bertha Shackleford, both of Omaha, December 17.

JAMES DELAVEN HEARD, M.D., to Miss Edith McIlvaine, both of Pittsburg, Pa., December 27.

JOHN M. SPAULDING, M.D., Salt Lake City, to Miss Ella Maxwell of Boise, Ida., December 24.

JOHN W. HAYES, M.D., Cleveland, to Miss Mary Mejer of Chicago, at Buffalo, N. Y., December 16.

JAMES MCCLURE RICHARD, M.D., Salt Creek, Tenn., to Miss Statira Gray of Retro, Tenn., November 21.

C. E. FOWLBE, M.D., Sparrows Point, Md., to Miss Geneva E. Isaacs of Ellicott City, Md., December 12.

FRANK EDWART ARTAUD, M.R.C., U. S. Army, to Miss Annie Alderslade Ball of Key West, Fla., November 9.

DIEDRICH JANSSEN MEENTS, M.D., West Point, Ia., to Miss Violet Ward of Dufur, Ore., at Fort Madison, Ia., November 22.

Deaths

Jeremiah Mason Main, M.D. New York University, New York City, 1859; attached to the U. S. S. *Constitution* at the time of the visit of Commander Perry to Japan; for forty years a practitioner of the Mexican frontier; United States pension examining surgeon at Laredo, Tex., for thirteen years; for fourteen years an attache of the United States Marine-Hospital Service; and for sixteen years city physician of Laredo; died at his home in that city, December 9, from senile debility, aged 84.

Charles E. Stone (examination, Medical Society of California, 1876); a member of the American Medical Association; for sixty years a practitioner of California; a member of the first State Board of Health of California in 1870; president of the Medical Society of Yuba and Sutter Counties; county physician of Yuba County, and superintendent of the Yuba County Hospital; mayor of Marysville in 1876-1877 and 1880-1881; died at his home in Marysville, December 10, aged 82.

Joseph Athanasius McDonald, M.D. Harvard Medical School, 1866; a member of the Massachusetts Medical Society; a member of the legislature from Charlestown in 1866, of the Charlestown School Board from 1869 to 1873, and for eighteen years a member of the Boston School Board; surgeon of the Ninth Infantry,, M. V. M. from 1870 to 1874; died at his home in Charlestown, Boston, December 8, from pneumonia, aged 70.

James M. Wheat, M.D. Albany (N. Y.) Medical College, 1853; a member of the Redlands (Cal.) Medical Society; secretary of the board of health and health officer of Redlands; formerly a resident of Minnesota; from 1875 to 1877 a member of the legislature, and from 1877 to 1887 a member of the senate; died at his home in Redlands, November 27, from cerebral hemorrhage, aged 85.

Napoleon Hickman, M.D. University of Pennsylvania, Philadelphia, 1862; of Philadelphia; a member of the American Medical Association; formerly demonstrator of anatomy in his alma mater; a surgeon of volunteers during the Civil War; United States pension examining surgeon; died at the home of his daughter in Ocala, Fla., December 9, from heart disease, aged 71.

Martin J. Thompson, M.D. University of Alabama, Mobile, 1872; formerly a member of the city board of health, president of the Mississippi State Medical Association, and president of the Lauderdale County Medical Society; died at his home in Meridian, December 5, from the effects of a fractured hip sustained in a runaway accident last winter, aged 65.

Presley C. Hunt, M.D. Georgetown University, Washington, D. C., 1891; formerly a member of the American Medical Association; neurologist to Providence Hospital, Washington; attending physician to St. Ann's Infant Asylum, and the Children's Country Home; died in Johns Hopkins Hospital, Baltimore, December 15, aged 39.

William Steptoe Christian, M.D. Jefferson Medical College, 1851; a member of the Medical Society of Virginia, twice orator, and president in 1904; a Confederate veteran; for several years superintendent of schools of Middlesex County; died at his home in Urbanna, December 15, aged 79.

William M. Holton, M.D. College of Physicians and Surgeons, New York City; 1852; a member of the Indiana State Medical Association; assistant surgeon of the Twenty-Fifth Indiana Volunteer Infantry during the Civil War; died at his home in New Harmony, December 12, aged 83.

David Williams Vander Burgh, M.D. University of Michigan, Ann Arbor, 1866; assistant surgeon of the Tenth Michigan Volunteer Infantry during the Civil War, and acting assistant surgeon, U. S. Army for a year thereafter; died at his home in Fall River, Mass., August 29, aged 68.

Albert R. Fouser, M.D. Hahnemann Medical College, Chicago, 1883; a member of the Desplaines Valley Medical Association; for two years assistant physician at the State Penitentiary, Joliet; died at his home in Canton, Ill., December 9, from disease of the gall-bladder, aged 56.

Ora C. McEwen, M.D. St. Louis College of Physicians and Surgeons, 1897; local surgeon for the Denver and Rio Grande Railway at Farmington, N. Mex., and later a practitioner of Aztec; died in the Territorial Hospital for the Insane, Las Vegas, December 12, aged 35.

Samuel E. Martin, M.D. Eclectic Medical Institute, Cincinnati, 1852; a pioneer practitioner of Kansas; surgeon of the Fifteenth Kansas Volunteer Infantry during the Civil War; died suddenly at his home in Topeka, December 8, from heart disease, aged 84.

Edmund Arthur Donnan, M.D. Jefferson Medical College, 1880; a member of the Medical Society of the State of Pennsylvania; a member of the staff of the Shenango Valley Hospital; died at his home in New Castle, December 14, from pneumonia, aged 55.

William E. Brown, M.D. College of Physicians and Surgeons, Baltimore, 1884; a member of the South Carolina Medical Association; for several terms intendant of the town of Manning; died at his home, December 5, from nephritis, aged 54.

Francis Vincent Ely, M.D. New York University, New York City, 1897; of Pittsburg; a sufferer from epilepsy; died at his home, December 13, from the effects of a gunshot wound of the right temple, self-inflicted with suicidal intent, aged 37.

James H. Denny, M.D. Harvard Medical School, 1867; formerly of Boston; a member of the Massachusetts Medical Society and visiting physician to the Boston City Hospital; died in Vienna, Austria, October 16, aged 71.

Thomas J. Collier, M.D. Tulane University, New Orleans, 1867; of Griffin; a member of the Medical Association of Georgia; died in a sanitarium in Atlanta, December 12, nine days after a surgical operation, aged 69.

William Raleigh Cherry, M.D. Vanderbilt University, Nashville, Tenn., 1901; a member of the Kentucky State Medical Association; died at his home in Morgantown, December 13, from appendicitis, aged 35.

William Church Dake, M.D. University of Nashville of Nashville, Tenn., 1872; a prominent homeopathic practitioner of Nashville; died at his home, December 9, from cerebral hemorrhage, aged 58.

Harriet A. Miner, M.D. Hahnemann Medical College, Chicago, 1890; of Evanston, Ill.; died in Chicago, November 6, from carcinoma of the breast, with metastases to the liver and spleen, aged 46.

Stefano Joseph Hickey, M.D. Jefferson Medical College, 1888; a member of the Medical Society of the State of Pennsylvania; died at his home in Philadelphia, December 13, from pneumonia, aged 45.

Jerome A. Hughes, M.D. University of California, San Francisco, 1883; in 1894, coroner of San Francisco County; died at his home in Mill Valley, Cal., December 5, from heart disease, aged 54.

Andrew Goddard, M.D. Memphis (Tenn.) Medical College, 1853; for twelve years surveyor of McClennan County, Tex.; a Confederate veteran; died at his home in Waco, November 30, aged 80.

Felix F. Porter, M.D. University of Pennsylvania, Philadelphia, 1859; assistant surgeon of the Fifth Tennessee Infantry, C. S. A.; died at his home in Paris, Tenn., November 27, aged 72.

William Lambert, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1884; formerly of LaCrosse, Wis.; died at his home in Chattanooga, Tenn., November 26, from pneumonia, aged 54.

William Payne (years of practice, Tex.); for more than 50 years a practitioner of medicine and law; died at his home in Frankfort, Ky., November 7, from senile debility, aged 96.

John Flagg Gardner, M.D. Jefferson Medical College, Philadelphia, 1849; a Confederate veteran; died at his home in Manassas, Va., November 12, from senile debility, aged 85.

Arthur Alexander Chance, M.D. Medical College of Georgia, Augusta, 1884; of Wadley, Ga.; died in the State Hospital, Milledgeville, July 16, from chronic nephritis, aged 42.

C. Perry Sayles, M.D. Michigan College of Medicine, Detroit, 1884; of Kalamazoo; died at Bronson Hospital in that city, December 10, from carcinoma of the intestine, aged 52.

Dexter A. Smith, M.D. University of Georgetown, Washington, D. C., 1884; died at his home in Irving Park, Chicago, December 16, from cirrhosis of the liver, aged 60.

Sarah Grattles Hiatt (license, Kansas, 1870; Texas, 1892); of Mound City, Kan.; died at the home of her niece in Kansas City, Mo., November 2, from peritonitis, aged 72.

William J. Bartmess, M.D. Reform Medical College, Macon, Ga., 1857; a retired practitioner of Ellsworth, Ind.; died at his home, December 3, from septicemia, aged 76.

James Hamilton Morrison, M.D. Texas Medical College, Galveston, 1867; of Hempstead, Tex., died in a hospital in Houston, November 20, after prostatectomy, aged 68.

Charles P. Godfrey, M.D. Geneva (N. Y.) Medical College, 1868; health officer of Cayuta, N. Y.; died at his home in that place, October 10, from tetanus, aged 67.

Cornelius Corboy, M.D. Miami Medical College Cincinnati, 1887, formerly of Cincinnati, died at the home of his sister in Sardinia, Ohio, December 5, aged 52.

James Franklin Dick, M.D. University of Tennessee, Nashville, 1878, died suddenly at his home in Dongola, Ill., December 2, from angina pectoris, aged 63.

George Washington Drawdy, M.D. Atlanta (Ga.) Medical College, 1883, of Jesup, Ga., died suddenly in a restaurant in that city, December 3, aged 60.

James W. Keath, M.D. University of Pennsylvania, Philadelphia, 1876, died at his home in Schaefferstown, Pa., October 15, from tuberculosis, aged 55.

Charles Tessier, M.D. Victoria University, Coburg, Ont., 1883; died at his home in Haverhill, Mass., November 30, from cerebral hemorrhage, aged 57.

Horace William Hammond, M.D. University of Michigan, Ann Arbor, 1876, died at his home in Luther, Mich., November 29, from paralysis, aged 61.

William L. Bettis, M.D. Marion Sims Medical College, St. Louis, 1895, died at his home in Harrisonville, Ill., November 26, from uremia, aged 45.

Rosalie Senftenberg, M.D. National Medical University, Chicago, 1894, died at her home in Weyauwega, Wis., October 28, aged 70.

Daniel V. Moyer, M.D. College of Physicians and Surgeons, Baltimore, 1882, died at his home in Maryland Line, Md., November 9.

James R. Berry, M.D., Tulane University, New Orleans, 1880, died at his home in Columbia, Miss., September 29, aged 54.

Jett Theodore Keith, M.D. Keokuk (Iowa) Medical College, 1901, died at his home in Wichita, Kan., November 30, aged 36.

Robert C. Blair, M.D. McGill University Montreal, 1865, formerly of Quebec, died in Chicoutimi, Quebec, November 12.

Julian E. Phinney, M.D. Rush Medical College, 1889, of Harrison, Neb., died in Norfolk, Neb., October 25, aged 50.

Edward Augustus Reed, M.D. University of Louisville, Ky., 1891, died at his home in Knoxville, Tenn., November 25.

Orin S. Bonsteel, M.D. Geneva (N. Y.) Medical College, 1850, died at his home in Ypsilanti, Mich., December 7, aged 85.

William B. Hardy, M.D. Jefferson Medical College, 1856, died at his home in Belleville, Kan., December 6, aged 78.

Miscellany

A Collecting Letter.—One of New York's prominent nose and throat specialists uses the following letter form as a note on statements of accounts past due. In his work, as in ours, says the *Dental Digest*, accounts sometimes run long past the date on which they should be paid. He practices where expenses are high and competition keen. Here, as everywhere, the value of a pleasant personality is great, and business procedures should be courteous as well as firm.

> *Dear Sir:* Permit me to draw your attention to the enclosed bill which has been rendered to you on —— (here are filled in the dates on which statements were rendered). It is customary for me to turn my accounts unpaid after six months to my attorney, Mr. John Smith, —— Broadway, New York City, as my practice does not permit me to give them personal attention after that time. I am sure this matter has simply been overlooked and that bringing it to your notice will secure it prompt attention.
>
> I am sending this letter by registered mail believing that I may have had your address incorrect.

The Doctor makes the following interesting comments on this letter and its effects: "This letter assumes their desire to pay. It puts part of the blame on them, and assumes part of it for me, as I say I may have had their address wrong. It makes some of them feel rather ashamed, and brings remittances from many. Once in a while some man will come in with one of these letters and say, 'What do you mean by sending me a letter like this?' and he will follow it up with a lot of talk. I let him talk it all out without interrupting him. Then I say, 'You musn't come into my office and talk to me like that, because I am a pretty decent sort of a fellow and don't deserve it. You must know that I am not in practice for the love of it. If I were, I should have transferred your account to the charity side of my ledger and you wouldn't like that. All that is necessary is that you send me a check, and we will be on good terms again.'"

The result of these tactful and firm methods is that in a long list of accounts, in a form of practice notorious for poor collections, this practitioner has less than a dozen old accounts, and nearly all of these are in process of payment by installments.

Efficient Cholera Prophylaxis.—The high degree of efficiency which characterizes the work of the Medical Department of the Army, says the *Army and Navy Journal*, has been nowhere better illustrated than in the Philippine Islands, where in the fiscal year 1909 there was not a case of cholera among the American troops, although the scourge counted thousands of victims among the natives. In the provinces there were 8,055 cases, with 5,524 deaths, these figures being below the actual number on account of the disposition of the natives to conceal all cases. In Manila there were 263 cases, with 211 deaths, the death percentage being slightly above 80. In numerous towns adjacent to military posts the disease was epidemic at some period during the year, but so thorough was the medical inspection and so vigilant the attention of the military surgeons that not a single case of cholera appeared among our troops. This achievement Surgeon-General Torney, in his interesting annual report, thus modestly refers to: "The absence of this disease among American officers and enlisted men and their families under such circumstances is excellent proof of the thoroughness and effectiveness of the sanitary measures employed. The Americans have been thoroughly imbued with the importance of abstaining from eating uncooked native vegetables and of using only sterilized water for drinking." In the native soldiery there were only nine cases with seven deaths, figures that testify to the salutary influence of the Army system of sanitation even with people accustomed for centuries to conditions of living that foster such diseases as cholera.

CLIPPINGS FROM LAY EXCHANGES

AUTOS ARE POLISHED—WHY NOT CHAUFFEURS?

Wanted: Situation as "Chauffeur" by a responsible, good looking, highly polished young physician, single and rare ability.—Advt., N. Y. *Herald*, November, 1910.

A HEARTQUAKE

"His death was attributed to an acute form of neuralgia of the heart which to medical men is known as pectoralis agitans."—Lorain (Ohio) *News Herald*, January 10.

GENERAL INDEX

All *reading matter* in THE JOURNAL from July to December, 1910, inclusive, is indexed here. (For Current Medical Literature Index see pages 2352 to 2410). "Deaths," "Book Notices," and "Society Proceedings" are indexed under these titles at the ends of the letters "D," "B" and "S." Matter pertaining to the Association is under "American Medical Association." With the above exceptions, all matter is indexed under the most important word of the heading that was used in THE JOURNAL, and also under the subject heading. For instance, abscess of brain will be found indexed under "abscess" as well as under "brain." Such titles as "ocular manifestations, etc.," have been indexed under "eye." Cross references have been made wherever this was possible. It is also well to remember that, in looking up a certain subject, related words should be consulted, for example, chest, thorax; skull, cranium; bowel, intestines. The letters used to explain in which department the matter indexed appeared are as follows: "E" editorial; "O" original article, "C" correspondence, and "ab" denotes an abstract of an article that has appeared in full elsewhere. *Names of authors* of original articles appearing in THE JOURNAL are not given in this index, but are included in the Index of Authors.

CURRENT MEDICAL LITERATURE

INDEX OF SUBJECTS

Explanation The *reading matter which appeared in* THE JOURNAL *is not indexed here*, except the original articles and the abstracts of original articles This index refers to the titles and the subjects of original articles published in the leading medical journals of the world, including THE JOURNAL, during the past six months The titles of the articles and the names of the journals in which they appeared were listed weekly in the Current Medical Literature Department, and it is to them that references are here made The figure in parentheses refers to the paragraph, the number following to the page in THE JOURNAL For instance, "Abdominal Aorta, Graft of Vena Cava on, (119) 1684—ab," refers to page 1684 of THE JOURNAL, on which is found in paragraph numbered 119, the title of the paper and the name of the author, viz, "Graft of Vena Cava on Abdominal Aorta A Carrel" This title is listed under the journal in which the article appeared, the *Annals of Surgery*, October, 1910 When "ab" follows a page number it indicates that the article was abstracted in THE JOURNAL, for instance, "Abscess, Liver, (89) 801—ab" On page 801, paragraph 89, will be found an abstract of this article, which appeared in *Surgery, Gynecology and Obstetrics* August, 1910 Titles of articles which appeared originally in THE JOURNAL are indicated in the index by an asterisk (*) before the page number, for instance, "Abscess, Appendicular, Localized Treatment of, *363," refers to page 363 of THE JOURNAL, on which is found the complete original article The index to authors of all articles, both original and those listed under Current Medical Literature, appears separately on pages 2411 to 2428 of this Index.

A

Abdomen and chest penetrating wounds of (16) 170
bullet wound in (23) 440
carcinoma large of right Fallopian tube palpable through (53) 532
drainage of into subcutaneous tissues, in ascites (30) 1935—ab
gunshot wounds of (64) 1322
laparotomy for removal of gauze sponge 9 months in (101) 169 ab
lower adhesions of, causes and indications for operation (151) 971
oxygen irrigation of continuous in abdominal surgery (64) 173—ab
painful spots in with chronic appendicitis (51) 441
palpation of improved technic for, (98) 175—ab
pneumonia with severe symptoms in simulating acute diseases of, (144) 852—ab
right lower quadrant of, surgical conditions of (72) 2097
upper diagnosis of chronic surgical lesions in (73) 1932—ab
upper, differential diagnosis of pathologic conditions in, (71) 2097
visceral anesthesias of tabes dorsalis and diagnosis of acute inflammatory conditions in *1427
wounds of, penetrating, illustrating recuperative power in natives of India, (11) 2310
Abdominal adhesions chronic neurasthenia due to operation, recovery, (10) 1325
adhesions postoperative, oil in, (89) 2015—ab
and pelvic surgery and hyperchlorhydria (4) 884
aorta graft of vena cava on, (119) 1684—ab
cancers distant signs of, (54) 723 ab
cavity, multiple hydatid cysts in, (131) 1331
cavity, new incision for operative procedures in (61) 252—ab
Cesarean section, status of, (80) 2097
contusions, (128) 170, (75) 2021—ab
crises due to pathologic changes in Meckel s diverticulum other than by obstruction band, (26) 2011
diphtheria (70) 1842—ab
disease, acute, rectal palpation in diagnosis of, (79) 169
disease, pancreatic reaction in, (2) 439—ab
drainage (155) 263, (86) 627 (110) 1422, (154) 1512
drainage in gynecology (36) 627
echinococcus cyst, ruptured, (26) 1599—ab
hysterectomy for cancer, end results of, (54) 2187—ab
hysterectomy for fibromyomata of uterus, (41) 532—ab
incision, new (61) 252—ab
incisions physiologically correct, (73) 540—ab
incisions self retaining retractor for (90) 1230
incisions transverse, (136) 254, (73) 2269—ab
injuries early diagnosis and treatment, (60) 532
injuries, internal, (16) 536
Abdominal insufficiency and neurasthenia prevention of, after delivery (83) 1230
operations active lobar collapse of lung after, (18) 1687—ab
operations on pelvic organs after results of, in 1 000 consecutive operations (43) 89—ab
operations organization and management of, (2) 2310
organs pathologic fixation or displacement of, and x ray diagnosis, (108) 444
pain clinical significance of, (39) 800
pain, diagnostic value of, (27) 884
palpation and auscultatory percussion, (71) 1762
palpation and pelvimetry, (174) 890
phlebosclerosis and slow progressive peritonitis with desquamation of epithelium all of traumatic origin (95) 1237
ptosis or constipation, gymnastic treatment of (100) 2277—ab
Section See Laparotomy
surgery, complications in, (94) 1932
surgery, continuous oxygen irrigation of abdomen in, (64) 173 ab
surgery, diagnostic errors in, (84) 169
surgery, Ephraim McDowell father of, (140) 888
surgery, important requirements in, (78) 719
surgery progress in, (109) 811—ab
surgical shock, new treatment for, (65) 1322—ab
suture, median re enforcement of, (76) 91
sympathetic, manual treatment of, (21) 531
symptoms, severe, pneumonia with, simulating acute diseases (144) 852—ab
trauma, location and nature of injuries of gastrointestinal tract following, (57) 1412
traumatism, rupture of intestine from, (158) 804
tumors, diagnosis of, (33) 1144
tumors, large, and anterior wall of abdomen, diagnosis by auscultation of adhesions between, (119) 895
wall, anterior, and large abdominal tumors, diagnosis by auscultation of adhesions between, (119) 895
wall after delivery and prevention of abdominal insufficiency and neurasthenia, (83) 1230
wall, causes of rigidity of, (101) 541
wall, fibroma sarcoma and fibromyoma of, (1) 971—ab
wall, hernia of, (36) 2312—ab
wall lower, and pelvic organs, conservative surgery of, *2215
wall, rigidity of (78) 1850
wall surgical emphysema of, (45) 1151
wall, varices in, (84) 630
wound, importance of care in closing (37) 1321—ab
wounds, stitch for overlapping fascia in closure of, (79) 253—ab
Abdominoperineal operation for rectal cancer, (6) 1598—ab
Abduction congenital defect of, with retraction of eyeball (105) 888
Abnormalities six, from dissecting room (20) 1766—ab
Abortion (68) 1939—ab
and ruptured tubal pregnancy, diagnosis of, (77) 1032—ab (24) 2034
death of parturient allowed to get up early after (119) 1942—ab
effect on of irritable ulcer of rectum in pregnant women, (88) 1763
induced, is it justifiable, (98, 99) 1414
induced suppurative catarrh in Fallopian tube after, (141) 1853
induced vaginal Cesarean section for (99) 977—ab
induced, legal regulation of, (142) 177
inevitable, (82) 253—ab
justifiable (32) 885
local anesthesia in, (143) 177
missed and labor, (85) 1682
septic, pathogenesis of, (117) 1331
septic thrombosis of pelvic veins following, (82) 2014
tubal, relics of, and their diagnosis, (71) 630—ab
when is it necessary? (27) 251
Abscess, alveolar, pathology and treatment of, *1255
and fistula, (31) 1688
appendicular, localized, treatment of, *363
around sinus and abducent paralysis with acute otitis media (102) 810
brain, (14) 88, (31) 434, (84, 95 96) 624, (45) 1054, (98) 1056, (16) 1680, (81) 1812, (91) 1843
brain in frontal lobe, secondary to ethmoiditis and frontal sinusitis (84) 624
brain of otitic origin, operative procedure of, (91) 1843
brain, operation, (31) 431
brain, traumatic, recovery after operation 7 months later, (38) 2186
cerebellar, (98) 1056
cerebral encapsulated (14) 88
cerebral, with chronic suppurative otitis media, (95) 624
does internal medication tend to abort or cure? (16) 620
epidural latent mastoiditis with, (96) 624
fecal, evacuation of, and ileosigmoidostomy, carcinoma of cecum removed after, (33) 1766
formation, osteal tuberculosis without, diagnosis and treatment of, (5) 2181
formation recurrent, autogenous vaccines in, (112) 1603
in frontal lobe of brain after chronic frontal sinusitis, (16) 1680
in left temporosphenoidal lobe, (81) 1842
liver, *500, (89) 801—ab, (85) 2014
liver, amebic dysentery with originating in Montreal, (129) 86
liver, amebic, prevention and treatment of, (104) 1684—ab
liver cases simulating, (122) 254
liver during or consecutive to typhoid, (80) 173—ab
Abscess liver, following acute appendicitis (3) 1148
liver, in boy of 8, operation, (159) 254
lung, pneumotomy for, (62) 356
of cornea ring (124) 351
of larynx, (110) 1844
pelvic, ante uterine, sequestration and drainage for, (81) 85
perigastric, hepatic gumma simulating (43) 348
perirectal, (149) 87
peritonsillar, cause and treatment (150) 971
retropharyngeal, (100) 86, (4) 1319—ab
submaxillary, caused by use of infected toothpick, (106) 1844
subperiosteal, in mastoid region treatment of, (144) 1601, (90) 1843
subphrenic (102) 887, (69) 1600—ab
subphrenic, complicating pregnancy with sloughing of spleen, (50) 256
subphrenic, originating in pancreas transpleural operation for, (50) 1923
tuberculous, diagnostic puncture in (72) 886
urethral and prostatic, posterior, surgery of, resulting fistula, (32) 531
Abscesses cold, puncture in treatment of, history of, (53) 1151
fixation in chronic lead poisoning, (97) 631—ab
liver, cholangitic, multiple cured by drainage of gall bladder, (108) 895
liver, recurring, (36) 2268—ab
liver rupture of, into lungs, (16) 1598
sinuses and fistulas bismuth vaselin paste for, (151) 889
Absorption in great omentum, (116) 2190
Acapnia and shock, (67) 85—ab (73) 2014
and shock, failure of circulation (73) 2014
as factor in dangers of anesthesia, (67) 85—ab
Acardius amorphus, (123) 1156
Accidental and industrial poisonings (95) 1851—ab
Accidents due to swiftly moving machines their automatic rational prevention, *2296
industrial, arousing latent internal disease in apparently sound individuals, (79) 975
industrial, to hands, (97) 1419
neuroses after, (70) 975
Accommodation See also Eye
Accommodation and ciliary muscle, (96) 2270
Accouchement See Delivery
Acetonemia in child, acute attack of, (32) 1765
Acetonuria and periodic vomiting in children, (152) 545—ab
Achlorhydria hemorrhagica gastrica, *1790
Achondroplasia, (48) 800—ab
Achylia gastrica, existing theories and new theory of etiology, (9) 884 ab
pyloric insufficiency and flora with, (129) 94
Acid See also Acids

Acid, acetic, and sodium carbonate seroreaction, (153) 178—ab
  acetic, clinical importance of differentiation of effusions and transudates by response to, (128) 262—ab
  acetic, formation of beta-oxybutyric acid from, (131) 1238
  benzoic, detoxification of, by optical isomers of leucin, (129) 970
  beta oxybutyric, formation of, from acetic acid, (131) 1238
  beta oxybutyric, formation of, in animal organism, (128) 633
  boric, influence of, on diastasic action, (70) 893
  boric, presence and utility of, in vegetable life, (37) 172
  Carbolic See Phenol
  citric, cultivation of Leishman bodies in blood from spleen with addition of, (152) 178
  hydrochloric, absence of, with blood in stomach secretion as symptom of chronic gastritis, *1790
  hydrochloric, free, in stomach, direct determination of, (48) 2274—ab
  Intoxication See Acidosis
  lactic, bacilli, influence of, on intestinal flora, (68) 258
  lactic, bacillus, culture of, in chronic specific urethritis, (7) 1320—ab
  lactic, in metabolism, (41) 1150
  lactic, therapy, (5) 2271
  nitric, intoxication from industrial inhalation of, (83) 1601
  nucleinic, little prophylactic efficacy in subcutaneous injection of, before laparotomies, (128) 1852
  nucleic, not reliable as prophylactic for puerperal fever, (145) 544
  oleic, and its soaps, action of, on blood, (12) 2017—ab
  oleic, presence of, in stomach content sign of gastric cancer, (96) 1602—ab
  Salicylic See also Salicylates, and Sodium Salicylate
  salicylic, and its preparations actions and uses of, especially in rheumatism, (67) 968
  Uric See Uric Acid
Acidity, gastric, estimation of, by effervescence on ingestion of alkali, (84) 91—ab
Acidosis, (6) 1686
  histologic determination of, (168) 898
  ileocolitis complicated by, *991
  in children, idiopathic, (37) 1767 ab
  non diabetic, clinical significance of, (100) 1231
  primary, recovery, (30) 2018
Acids See also Acid
Acids, aspartic and glutaminic, separation and estimation of, (88) 1413
  dibasic, unsaturated, behavior of molds toward stereo isomers of, (118) 1324
  fat, hemolytic, free, in liver with acute yellow atrophy and phosphorus poisoning, (90) 92
  fatty, and fat in feces, new method for determination of, (129) 254 ab
  fatty, higher, carbohydrate esters of, (130) 254
  fatty, mode of oxidation of phenyl derivatives of, a correction, (52) 719
  fatty, volatile, and esters, production of, in cheddar cheese and relation to development of flavor, (131) 254
Acne, colon lavation in, (10) 806—ab
  rosacea, eye symptoms in, so called rosacea keratitis, (99) 802
  vulgaris, acne bacillus suspensions for, (118) 2270—ab
Acnitis and lupus of face, miliary, disseminated determination of tubercle bacilli in, (86) 894
Aconite, (17) 1228, (17) 1320, (13) 1410
  poisoning, (28) 1935
Acromegaly, (142) 1934
  and goiter, (57) 1321
  tumor of, hypophysis cerebri without, (157) 1063
  with hypertrophied heart, (9) 1686
Actinomycosis, (15) 965
  abdominal, fatal, case of, (151) 545
  etiology of, (2) 530—ab, *1261
  experimental production of, in guinea pigs inoculated with contents of carious teeth, (2) 530—ab
  intralaryngeal, primary, (75) 1842—ab
Actinomycosis of liver, (132) 1852
  of orbit, (78) 540—ab
  of tongue, (64) 1328
  parametritis due to, (153) 1512—ab
  potassium iodid in, (10) 1503
  serodiagnosis of, differential importance of, (66) 91—ab
Activator, radiologic, (97) 725
Active principles vs gross drugs, (8) 1028
Adams Stokes syndrome, (58) 1112, (35) 2273
  Morgagni, symptom complex and its differentiation in electrocardiogram, (91) 1370
  syndrome, diffuse, purulent, ventriculo septal myocarditis with, *1065
  syndrome with complete heart-block without destruction of bundle of His, (41) 168—ab
Addison's disease, (102) 86, (4) 432
  and hyperplasia of lymphatic apparatus and thymus, (132) 261—ab
  with amyloid or occlusion of suprarenals or hypernephroma, (92) 1330—ab
Address historical, at bicentennial of Berlin Charité Hospital, (85) 92
Adenitis, acute, radiotherapy in, (51) 1848
  in children, cervical, tuberculous, vaccine therapy of, (28) 1760
  suppurative, of glandular origin, radiotherapy of, (68) 91
  suppurative, under sternocleidomastoid treated with streptococcus vaccine, (6) 1228
  tuberculous, cervical, treatment of, at Sea Breeze Hospital, (45) 434
  tuberculous, obscure, (149) 438
Adenocarcinoma of vagina, primary, (166) 1771
Adenoid tonsils, hypertrophied, an etiologic factor in backward children, (41) 1500
  and tonsil hypertrophy as factor in arresting development of teeth and alveolar processes, (101) 1414
  growth and tonsils, fatality following removal of, (37) 1052
Adenoids and tuberculosis, (173) 264—ab
  plea for prevention of, (76) 1413
  symptoms and effects of, (104) 436—ab
  value of early diagnosis and treatment of, (162, 163) 87
Adenoidectomies, causes of failures in, (16) 1051
Adenomata, multiple, (84) 1763
  multiple, of rectum, pathology of, (6) 884, (85) 1763
Adenopathy in child, bronchial, tuberculous, early diagnosis of, (11) 1765
Adhesions, abdominal, chronic neurasthenia due to, operation, recovery, (10) 1325
  abdominal, postoperative, oil in, (89) 2015—ab
  between large abdominal tumors and anterior wall of abdomen, diagnosis by auscultation, (119) 895
  of lower abdomen, causes and indications for operation, (151) 971
  prevention of, *312
Adiposis and lipomatosis, (85) 532
  Dolorosa. See also Obesity
Adiposis dolorosa, (86) 169, (26) 256
  dolorosa in mother and daughter, *1373
Administration of drugs variation of dosage dependent on method of, *746
Adnexa Uterine See Ovaries and Fallopian Tubes
Adnexitis See Oophorosalpingitis
Adolescence, albuminuria of, (96) 533
  and sex problem, (66) 1682
  in girls, chemical tendencies of, (116) 436
Adrenal See also Adrenals
Adrenal activity, thyroid secretion as factor in, *1724
  principle, action and uses of, (147) 1845
  sarcoma of, (13) 965
  tuberculosis, primary, in juvenile general paresis with meningeal infection, (13) 798
  tumor of, with metastasis in orbit, (166) 1503
Adrenalectomy and glycosuria, (68) 84
Adrenalin See also Epinephrin
Adrenalin and spartein, influence of intravenous injections of, on dog's heart, (128) 971—ab
Adrenalin, continuous intravenous infusion of, (38) 2101
  in vomiting after chloroform anesthesia, (8) 2098—ab
  saline infusion, possible dangers of, (175) 1855—ab
Adrenals: See also Adrenal
Adrenals, induction of pancreatic activity by removal of, (34) 2012—ab
Adult See also Adults
Adult and child life, essential differences between physical findings in, *1008
  hypodermic use of quinin in, in malarial hematuria, (155) 971
Adulteration of organic remedies, historical sketch of, (136) 812
Adults, constipation in, (26) 88

Albumin bodies and fat deposits in liver, (57) 723
  content in urine, rapid determination of, (148) 1332—ab
  expectoration after thoracocentesis, (72) 2274
  in sputum not always due to tuberculosis, (100) 977
  milk in infant feeding, (107) 93—ab, (94) 444—ab, (84) 541—ab, (152) 898—ab
  nephritis without, (18) 621—ab
  reaction in tuberculous sputum, (150) 634—ab
  vegetable, putrefaction of, (148) 361
Albuminoids in urine and parturients, (60) 539
  sensitiveness of organism to, (110) 1769
Albuminuria of adolescence, (96) 533
  orthostatic, influence of creeping exercises on, (71) 2021—ab
  regulatory, (121) 896—ab
  significance of, in diagnosis, (46) 355
  transient, favorable sign after laparotomy for peritoneal tuberculosis, (178) 1064—ab
Albumosuria, alimentary, (151) 1240
Alcohol, action of, on human system, (44) 355—ab
  action of, on normal intact unanesthetized animal, *372
  action of, on powers of perception and memory, (167) 362—ab
  an active cause of insanity, (83) 719
  analeptic action of, in pathologic conditions, (82) 174—ab
  and legal medicine, (16) 1498
  and muscular fatigue, influence of, on normal defenses, (114) 350 ab
  and nephritis, *279
  as medicine in heart disease, (107) 260—ab
  effect of, on psychoneuroses, (38) 2184
  effects of from scientific standpoint, (36) 251
  effects of moderate doses of, (23) 171
  effects of, on nervous system, (164) 352
  ethylic and amylic, differentiated, (149) 1233
  gastritis due to, and experimental gastritis in animals, (27) 799
  group, physiologic action and therapeutic uses and abuses of, (149) 1233
  infiltration of superior laryngeal nerve, durable anesthesia of tuberculous larynx by, (85) 1941 ab
  influence of, on nitrogenous metabolism in men and animals, (66) 2014—ab
  influence of, on syphilitic serum in Wassermann reaction, (144) 813
  injections in neuralgias, (94) 1056, (11) 2267
  injections in neuralgia, technic for, (75) 630—ab
  injections in superior laryngeal nerve in dysphagia of laryngeal tuberculosis, (14) 354—ab
  intoxication, rupture of bladder during, (122) 1156
  in therapeutics, (84) 719
  only narcotic poison, (119) 1414
  paste for sterilization of hands, (87) 1237
  pharmaceutical action and therapeutic uses of, (152) 804
  physico chemical hypotheses in regard to pharmacologic and toxic action of, (139) 95
  physiologic action, uses and abuse of, in circulatory disturbance of acute infections, *2034
  problem as seen in ancient and modern times, (14) 1326
  problem, education as essential as legislation in solving (149) 1233
  question, (46) 348
  sterilization of hands without preliminary scrubbing, (86) 357
Alcoholic extracts and lipoids, with active and inactive serum in serodiagnosis of syphilis, (29) 2011—ab

Alcoholic fermentation, influence of concentration of saccharose in, (33) 2186
neuritis in children, (87) 1850—ab
psychoses, (70) 1116—ab
vapor mixed with oxygen, therapeutic use of, (6) 2017—ab
Alcoholics, chronic, plea for state institution for treatment of, (66) 532
Alcoholism, amnesia due to, (19) 1051
and drug addictions, (177) 438
and its associated evils, instruction of academic students of both sexes in dangers of, (22) 2267
chronic, clinical study of 460 cases, *279
chronic, nervous system in, (5) 2016
etiology of, (113) 1503
hypertension due to, treatment of, by D'Arsonvalization, (87) 1055
Aldehyd, acetic in alcoholic fermentation, yeast fungi and, (36) 172
acetic, not normal product of alcoholic fermentation, (35) 172
Alexander Adams operation, local anesthesia for, in 13 cases, (106) 1155—ab
Algal pollution in reservoirs of Panama Canal Zone, control of, (170) 1415
Alien aggressions, influence of, on experimental Malta fever, (146) 95
Aliens, pupil conditions in, significance and suggestions, (74) 801
Alimentary See also Gastro intestinal
Alimentary calcification, experimental, of arteries, (157) 898
Alimentation, duodenal, (13) 434—ab, (97) 1595
Alkali, effect of, on melanin, (65) 1682
estimation of gastric acidity by effervescence on ingestion of, (84) 91—ab
Alkalies, caustic, esophageal stenosis following swallowing of, *1857
earthy, in blood of dyspeptic infants, (92) 1769

Antiformin chloroform, technic for staining tubercle bacilli, (95) 2021
  cultivation of tubercle bacilli directly from sputum by use of, (134) 352—ab
  method, ether acetone, of sputum examination, (90) 541
  method, Uhlenhuth Hune, for determining tubercle bacilli in sputum, (106) 175
  resistance of Spirochæta lymphatica to, (12) 884
  test for scanty tubercle bacilli in scraps of tissue, etc (71) 724
Antigen, typhoid bacilli as, in experimental research, (69) 2103
Antigenic crystal from luetic liver, complement fixation with, *1264
Antigens and serums, technic for preservation of, (103) 1941—ab
Antiketogenesis, nature of, and action of glycol aldehyd and glycerin aldehyd in diabetes mellitus, *2109
Antimony thioglycollic acid compounds, efficacy of, in experimental trypanosomiasis, (87) 1843—ab
Antipyretics and narcotics, value of combinations of, *311
Antipyretics symptomatic acting, phenol and camphor as prototypes of, (1 0) 1510
Antiseptic, oxygen as, (60) 1140—ab
Antiseptics and germicides, fallacies in understanding of, especially mercuric chlorid, *303, (111) 2016
Antitoxin, administration of cutaneous anaphylactic reaction as contra indication to, *776
  diphtheria, (63) 723
  diphtheria, absorption of, (109) 1941
  diphtheria, in hemophilia, (104) 2276
  diphtheria, in local treatment and prophylaxis of infectious processes, (66) 356—ab
  diphtheria, intravenous injection of, (89) 976—ab
  diphtheria, unusually quick rash following injection of, *1200
  large quantities of, in tetanus, *1613
  Tetanus See also Serotherapy of Tetanus
Antitrypsin, importance of determination of, in gynecology, (169) 1771
Antitryptic index, measuring of, (4) 353—ab
Antrum, maxillary, disease of, (11) 1143—ab
  maxillary, disease of, office treatment of, (11) 2310
  maxillary, size of, and position of permanent teeth, (19) 1765
  maxillary, suppuration of, (16) 88, (2) 1759
Anuria after gall stone operations, (135) 1852
  complicating hemoglobinuria, surgical condition, (77) 1230
  postscarlatinal, in child for 5 days, (12) 1690
Anus See also Anorectal, and Rectum
Anus and lower end of rectum, congenital absence of, (6) 717—ab
  and rectum, malformations of, (74) 1763—ab
  artificial, deformity of child's thorax due to influence of, (100) 259
  evils of forcible dilatation of, (102) 1602—ab
  imperforate, (57) 169
  importance of isolated local anesthesia of prudendal nerve in operations on, (137) 95—ab
Aorta, abdominal, graft of vena cava on, (119) 1684—ab
Aorta and heart, orthodiagraphy in pathologic conditions of, (27) 1499—ab
  and pulmonary artery, experimental research on action of measures for resuscitation after temporary occlusion of, (99) 260—ab
  aneurysm of, behavior of elastic tissue with, (113) 1603
  aneurysm of, communicating with superior vena cava, (8) 1686—ab
  aneurysm of, from articular rheumatism, (85) 724
  aneurysm of, dissecting, (121) 2190
  aneurysm of, treatment of, (26) 1499—ab
  arch of, and its branches surgery of aneurysm of, (24) 1052
  cause of dilatation of heart and high blood pressure with arteriosclerosis in, (83) 2275
  dilatation of, (24) 1499—ab
  influence of depressor nerve on elasticity of, (93) 1508
  suture of, experimental, (75) 1507
  thoracic, and heart, experimental surgery of, (71) 435
  thoracic, descending, aneurysm of, (52) 251
Aortic insufficiency and stenosis, changes in adjoining endocardium with, (87) 174
  insufficiency, tongue pulse with, (90) 1769—ab
  regurgitation, (21) 2186
  regurgitation, difference between systolic pressure in arm and leg in, (139) 625—ab
  valve, traumatic laceration of, (90) 174—ab
Aphasia, (107) 720, (87) 969
  and other disorders of speech, (67) 624, (21) 973
Aphemia, prognosis, diagnosis and treatment, (21) 973
Aphonia, hysterical, treatment, (89) 809—ab
  persistent, following laryngitis, Faradic current in, (31) 2018—ab
Apnea, fatal, and shock problem, (115) 970—ab
Apnea in infant, prolonged, repeated, without apparent cause, (20) 2099
Apomorphin, beta chloromorphid associated with [illegible] as antagonist to, (96) 1154
Apoplexy of nervous system, (72) 968
Apparatus See also Instrument
Apparatus and exercises in scoliosis, (74) 1768
  and orthopedic dressings, (45) 719
  blood pressure, criticism of, *815
  electrode cage for therapeutic use of static electricity, (114) 1237
  extraction, new form of, (135) 254
  flexible contact diaphragm and protective shield for x ray tubes, *499
  foot and leg table, and hand table, for surgical out patient departments, (89) 1932
  for accurately fixing blood slides by heat, *2299
  for administration of rectal and pharyngeal anesthesia, (160) 87—ab
  for applying artificial heat, *1413
  for conservative office treatment of fractures of patella, olecranon and calcaneum, (163) 1854—ab
  for differential pressure, (149) 545—ab
  for ether anesthesia, (117) 1596
  for general anesthesia with differential pressure, (77) 1507
  for inducing artificial respiration, (84) 2022—ab
  for supporting and holding head and shoulders in cerebellar and high spinal operations, *1859
  for urethroscopy and electrolysis, (46) 90
  freezing microtome, (81) 1502—ab
  metal brace for fracture of long bones, (34) 722
  moving picture, durable, for recording movements, (96) 725
  orthodontia, in fractures of maxillary bones, (84) 1843
  orthopedic, staff for use in, (58) 1506
  pipette pump for Wassermann Neisser Bruck serodiagnosis of syphilis and general laboratory work, (99) 1147
  pneumatic illuminated infantile sigmoidoscope, *314
  portable, for sterilization of drinking water of troops in field, (78) 443
  simple and inexpensive device to prevent contamination of sterile solutions, *127
  simple, for estimating fermentation in feces, (52) 355
  staff for use in orthopedic appliances, (58) 1506
  suction, in puerperal endometritis, (120) 1509
  suggested bunk tray, (121) 533
  universal x ray frame, (14) 1143
Appendectomy and hysterectomy in patient of 12, (16) 1416—ab
  hernia in cicatrix after, frequency of, (74) 540
  hernia, inguinal, following, *17
  immediate, in suppurative appendicitis, safety of, (25) 536
  internal, (8) 890
  prophylactic, (110) 444
  prophylactic, advantages of, (154) 263—ab
  shortening and fastening of cecum supplementary to, (35) 722
Appendices epiploicæ torsion and strangulation of, in hernial sacs, (56) 807
Appendicitis, (62) 252, (112) 444, (146) 447, (147) 545 (116) 625, (111) 1414—ab, (6) 2310
  acute, diagnosis and treatment of early stage of, (115) 895
  acute, hepatic abscess following, (3) 1148
  acute, treatment of, (198) 1856
  acute, within 10 hours after delivery, (19) 2311
  and gall stone disease, inter relationship of, (64) 1146
  and intestinal obstruction, pregnancy complicated by, (22) 536
  as complicating pregnancy, (123) 1414
  as factor in inflammation in biliary apparatus and in cholelithiasis, (142) 897
  cause of death after operation for, (4) 1148—ab
  chronic, (37) 355—ab
  chronic, due to movable cecum, cecopexy for, (110) 1852

- Appendicitis, chronic lead poisoning as diagnostic factor in, (30) 1840
  - chronic, painful spots in abdomen with, (51) 441

Atrophy and hypotrophy, severe forms of, in infants, treatment with milk at 108 C, (53) 1058
  chorioidal, in myopia, (56) 1930
  isolated, of muscle as diagnostic symptom for localization of tuberculous foci in bone, (152) 361—ab
  muscular, cerebral and spinal, muscle findings in, (57) 2274
  muscular, electricity in, (53) 1151
  muscular, progressive, following malaria, (153) 417
  of bones, fibrous (118) 1603
  of disuse, (89) 1595
  of optic nerve, simple, indications for mercurial treatment in, (126) 176—ab
  syphilitic, multiple, of skin, (157) 178
  yellow, acute, and phosphorus poisoning, free hemolytic fat acids in liver with, (90) 92
  yellow, acute, in secondary syphilis, (115) 1422
  yellow, acute, of liver, *368, (46) 623, (103) 1595
  yellow, of liver, acute, due to anesthol poisoning after operation for ileocolic intussusception, (122) 1684
Atropin, (111) 1232
  in dysmenorrhea, (118) 2278—ab
  in eye diseases, use and abuse of, (36) 348
  indications for, in internal medicine, (134) 1239—ab
  prophylactic action of, in immediate anaphylaxis of guinea pigs, (90) 1413—ab
Attitudes, faulty, prophylaxis and cure of, by utilizing children's school book bag, (90) 976—ab
Auditory canal and concha, incision and resection of, after petromastoid operation, (51) 537
  external, and membrana tympani, anesthesia of, with ethyl chlorid spray, (5) 432
  external, atresia of, (89) 624
Auditory meatus external, affections of, (79) 349
Auricle pulsation within esophagus, registration of, (45) 1328
Auricles, fibrillation of, and extrasystoles of ventricles (35) 2186
Auscultation and percussion of chest, importance of neck and chest muscles in production of phenomena from, (24) 2182
  how to distinguish systole from diastole in, (79) 1236
  in diagnosis of fractured ribs, (99) 1595
Auscultation of adhesions between large abdominal tumors and anterior wall of abdomen, diagnosis by, (119) 895
  tube, special, tuning fork tests with, (108) 1844
Auscultatory percussion and abdominal palpation, (71) 1762
Autochthonous amebic dysentery, (62) 1151
Auto infection, obstetric, (95) 2190—ab, (52) 2187
Auto intoxication, (119) 625, (20) 2267
  and allied intestinal troubles, *559
  dietetics and therapeutics of, (121) 970
  gastrointestinal, and mucous enterocolitis from viewpoint of surgery, (79) 1230—ab
  in diabetes mellitus, determination of degree of, by Ronchese Malfatti test for ammonia in urine, (103) 725
  of epilepsy, (28) 1327
Autolyses of physicochemical methods, study of, (55) 719
Autolysis and metabolism, (107) 1508
  changes in hemosiderin content of rabbit's liver during, (82) 1146
  of liver, influence of lipoids on, (99) 1060
Automatism, sensory, psycho analysis of, (71) 1055
Automobile fracture, (45) 1229
  influence of use of, on upper air passages, (1) 884—ab
Autopsy See Necropsy
Autopsychology of manic depressive, (30) 1680—ab
Autoserotherapy and heteroserotherapy, (58) 1236
  in fluids in serous cavities, (29) 1929—ab
  with ascitic effusion, (46) 441—ab
Autotoxemia, (119) 625, (20) 2267
Autovaccine in traumatic infections, (94) 436
Autovaccines in nasal accessory sinus infection, (75) 1322
Axilla, radioscopic triangle in, in pneumonia in children, (54) 90
Azoospermia, actual and apparent, (53) 2020—ab

B

Baby See Infant
Bachman, Robert, (77) 2014
Bacilli See also Bacillus
Bacilli, acid fast, in wind instruments, their importance in diagnosis, (115) 260
  diphtheria, differential stain for, (146) 254—ab
  lactic acid, influence of, on intestinal flora, (68) 258
  lactic acid, in local therapeutics and prophylaxis, (47) 1328—ab
  lactic acid, what they are and what they are supposed to do, (3) 965—ab, (58) 967
  leprosy, in stools, (200) 1856
  on faucets liable to prove source of error in sputum examination, (59) 974
  paracolon, infection from, (111) 358
  paratyphoid and Gärtner group in non specific disease, (107) 358
  paratyphoid B group, importance of, in human and animal pathology, (64) 443—ab
  paratyphoid, gastro enteritis due to, (12) 2185
  paratyphoid, modification of agglutinating power of, (84) 259
  tubercle, acid fast, and other forms of bacterial life, (1) 1928—ab
  tubercle, are they excreted through bile? (29) 966—ab
  tubercle, bacteriolysis of, (75) 1329
  tubercle, biology of, (53) 1417, (76) 1939, (54) 2274
  tubercle, bovine and human, meiostagmin reaction in differentiation of cultures and infection, (141) 1062
  tubercle, bovine and human, reaction curve of, (25) 1592—ab
  tubercle, bovine and human types of, relative importance of, in different forms of human tuberculosis, (26) 1592—ab
  tubercle, chloroform - antiformin technic for, (65) 2021
  tubercle, determination of, in disseminated miliary lupus of face and acneitis, (86) 894
  tubercle, determination of, when very scanty, (97) 92
  tubercle, determination of, with lupus erythematodes, (83) 809
Bacilli, tubercle, emulsion, sensitized, (89) 92
  tubercle, enrichment medium for, (125) 115
  tubercle, in blood, (145) 1512
  tubercle, in blood, diagnostic importance, (93) 358—ab
  tubercle, in calcified foci, (81) 1850
  tubercle, in cutaneous lesions, (88) 1119
  tubercle, in feces in tuberculosis, (12) 721—ab
  tubercle, in sputum, antiformin method for determination of, (106) 175, (131) 352—ab
  tubercle, in tissues and changes in their property of being acid fast, (78) 1060
  tubercle in tissue, antiformin test for, (71) 724
  tubercle, newer methods of enrichment and staining of, (146) 813
  tubercle, not found in urine in pulmonary tuberculosis, (38) 2273
  tubercle, paradox of, (6) 318
  tubercle, secondary infection with, and their saphrophytic growth, (101) 632—ab
  tubercle, sputum examination for, (106) 175, (18) 251—ab, (134) 352
  tubercle, staining of, improved technic for, (109) 260
  tubercle, staining technic for differentiation of, (58) 974
  tubercle, teeth and alveolar processes as points of entrance for, *195
  typhoid and paratyphoid, in stools, technic for determination of, (48) 411
  typhoid, as antigen in experimental research, (69) 2103
  typhoid, latent and chronic infections with, (33) 973
Bacilluria, typhoid, chronic, relation of typhoid spermatocystitis and prostatitis to, (93) 349—ab
Bacillus carrier, diphtheria, increasing difficulty of, (36) 892
  former, dysentery Y bacillus in intestines and liver of, (40) 2101
  typhoid, autopsy of, (174) 264—ab
  typhoid, bactericidal power of blood serum of, before and during active immunization with typhoid vaccines, (54) 1322—ab
  typhoid, detected in connection with epidemic of typhoid, (19) 1415
  typhoid, dog as, (53) 629—ab
  typhoid, probably cause of spread of disease, by milk infection, (6) 1325
Bacillus carriers and epidemic cerebrospinal meningitis, (160) 898—ab
  diphtheria, (22) 966, (9) 2185
  dysentery, (8) 2185
  typhoid, (23) 1234
  typhoid, and public health, (69) 887—ab
  typhoid, treatment of, *1708
  typhoid, prophylaxis of, by treatment of convalescents with potassium iodid or arsenic trioxid, (101) 1330
Bacillus, acne, suspension of, for acne vulgaris, (118) 2270—ab
  colon, acute pyelitis due to, in infancy, (27) 1150
  colon, as saprophyte and morbid agent in man, (102) 1330
  colon, human, strains of, and autogenous bacteria, rectal instillations of, in chronic intestinal putrefactions, (2) 1319—ab
  colon infection of meninges with primary adrenal tuberculosis in juvenile general paresis, (13) 798
  colon infection of operation wound, *1519
  colon infection of urinary tract, (112) 1237
  colon infection of urinary tract complicating pregnancy, (42) 892, (32) 1057
  colon, infections of urinary tract in infancy and childhood, (9) 1765, (40) 2095, (55) 2096—ab
  colon infections, generalized, (72) 975
  colon infections, recognition and comparative frequency of, (3) 1934
  colon, inhibition, attenuation and rejuvenation of, (51) 1054—ab, (162) 1414
  colon, on food, (39) 2101
  colon, pancreatin bile salt medium for detection of, in water, (165) 1415
Bacillus, colon, septicemia, (78) 91
  diphtheriæ on swabs, longevity of, (160) 1115
  dysenteriæ, agglutinins of, persistence of, (10) 798
  fusiform, and Spirochæta denticola, symbiosis of, partial gangrene of left index finger due to, *857
  fusiformis in membranous affections of throat, Vincent's angina, (98) 887—ab
  gas, causing diarrhea, test for, (11) 1591—ab
  hemophilic, found in urinary infections, (52) 1054—ab
  influenzæ, present status of, (43) 1936—ab
  Koch's, is it a cause of cancer? (5) 884—ab
  lactic acid, culture of, in chronic specific urethritis, (7) 1320—ab
  lactic acid, planting, (107) 625
  leprosy, cultivation of, and experimental production of leprosy in Japanese dancing mouse, (84) 1147—ab
  of hog cholera, immunity of rabbits to, (32) 2186
  subtilis, infection with, simulating miliary tuberculosis, (136) 1331
  typhoid, recognition of, by complement fixation, (13) 2185
  Y dysentery, in intestines and liver of former bacillus carrier, (40) 2101
Back, pain in, diagnostic significance of, (137) 971, (71) 1230
  pain in lower part of, in hip and extending down thigh, (104) 624
Bacteria, air, enumeration of, (130) 351—ab
  anaerobic, infections with, (83) 1060
  autogenous, and strains of B coli communis, rectal instillations of, in chronic intestinal putrefactions, (2) 1319—ab
  capsulated, in body fluids, staining of, (2) 2094—ab
  destruction of, and splitting of fat, relations of lymphocytes to, (139) 1062
  elimination of, from blood, through wall of intestine, (32) 2011—ab
  hitherto supposed not to have capsules, demonstration of capsule for, (113) 978
  isolated from tonsils, experimental study of, *26
  liquefying, viscosimeter as aid in detection of, (28) 1593—ab
  pathogenic, in urine, (24) 348
  transmission of, by flies and epidemic of bacillary dysentery, (17) 2267—ab
Bacterial and body enzymes, investigation on inter relation of, and their respective antibodies, (37) 2095
  content of ice cream, (21) 806—ab
  disturbances of digestion and consequences thereof, (41) 355
  examination, early, of secretion from post nasal region, importance of, in scarlatina, (11) 2267
  flora of nasal mucosa in rhinitis, *1091
  immunization, present status of, (59) 84
  infections in infants and children, vaccines in, (3) 717—ab
  integrity of collodion sacs, (37) 1761—ab
  invasion and preventive medicine, Pasteur contribution to, (32) 1840
  invasion, influence of, (155) 1597
  pollution of atmosphere by mouth-spray, investigation of extent of, (156) 1415—ab
  therapy, points in, (39) 83, (49) 1841
  toxins, influence of, on animal tissue, (115) 1603
  vaccines, (144) 170
  vaccines and serotherapy in puerperal septicemia, (81) 1932—ab
  vaccines, hypodermic and intramuscular inoculation of, as demonstrated by experiments with typhoid vaccine, (12) 354—ab
  vaccines in children's diseases, (126) 1414—ab
  vaccines in diseases among aged, (2) 1590—ab
  vaccines in pyogenic infections of urinary tract, (22) 1320
Bactericidal substances extracted from normal leucocytes, (128) 351—ab
Bacterin, Neisser, reputable stock, in chronic gonorrhea, (80) 2014

Baterin therapy in urethral and prostatic infections, (149) 804
Bacterins and tuberculins in mixed suppurative bone and joint disease, (49) 435—ab
  antigonococcus, and antigonococcus serum, (67) 1230
  or vaccines in ocular tuberculosis and corneal infections, (124) 1764
Bacteriologic and serologic work, vacuum bottles as aid in, (125) 94
  complement, (74) 1939
  examination of blood, (121) 633
  examination of blood and blood picture, importance of, in puerperal infection, (70) 91
  examination of conjunctival sac previous to cataract extraction, (101) 802
  findings, constant, in lupus, (111) 260—ab
Bacteriology and Rudolf Virchow, (97) 1851
  of acute respiratory infections in children as determined by culture from bronchial secretion *1241
  of bacillary dysentery, aspects of, (12) 1143—ab
  of epidemic summer diarrhea, (27) 1234—ab
  of gastro intestinal tract, (37) 167
  of soured milk (6) 2271
Bacteriolysis of tubercle bacilli, (75) 1329
Bad Nauheim waters, therapeutic effect of, (8) 1679
Balanitis, gangrenous and erosive, (180) 1772
Balantidium coli infection, (18) 83, (33) 1760—ab
  dysentery, (81) 1055
Baldness, premature symptomatic and rational treatment (103) 533—ab
Ball, metal, implantation of, in Tenon's capsule (105) 1503
Ballottement, suprahepatic sign of echinococcus cyst in liver, (39) 722—ab
Balneotherapy in urinary disease, (79) 173
Balsams use of, in cystitis and gonorrhea, (20) 171
Banana flour and plantain meal for children with diarrhea, (179) 890—ab, (70) 1230—ab
  as food for infants, (15) 1765
Bandage for cone shaped surface, *217
  handkerchief, improvisation of roller bandage from, *857
  roller, improvisation of, from square or handkerchief bandage, *857
Bandits, car barn, (12) 965
Banti's Disease See Splenic Anemia
Bantock, G G, M D, formerly surgeon to Samaritan Free Hospital, London, contributions to medical and surgical literature by, (37) 434
Bath, full, source of infection for parturients, (166) 1063
  natural processes for regulation of temperature of body in, (111) 632
  water in vagina, (55) 2187
Baths action of, on size of heart, (105) 542
  carbonated, cardiovascular modifications from, (46) 807, (124) 1062
  electric light, incandescent, readily improvised, (111) 542
  hot, in whooping cough, (143) 1512—ab
  incandescent light, (73) 975
  mud, oxygenated, (107) 632
  oxygenated and carbonated, comparative size of bubbles in, (144) 360
Beaumont and Alexis St Martin, (175) 890
Bedside teaching, importance of, *638
Bedside Widal test, (6) 1759—ab
Beef animals phosphorus in, (134) 254, (57) 719
  myocardium seroreaction with extract of, in diagnosis of syphilis, (134) 446—ab
Bee sting treatment of rheumatism, (10) 720—ab, (35) 1688
Beethoven, deafness of, (108) 632—ab
Bell Sir Charles (63) 252
Belt, perineal, for retention of dressings in situ (134) 1764
Benzidin test for blood, (46) 2101
Benzin iodized, irritation from in places where it does not evaporate, (93) 1940
Beriberi (164) 804 (149) 971
  and food salts (150) 971
  and phosphorus starvation, (147, 148) 971—ab
Beriberi and white rice, experiment with parrots (43) 1151
  epidemic of, (163) 804—ab
  etiology of, (144, 145) 971—ab
  in nursing infants, etiology of, (44) 1840
  in Siam, (146) 971
Berlin Medical Faculty, centennial of, (123) 1770, (183) 1850, (157) 1853

hydrochlorid and quinin for local anesthesia, (80) 319, (34) 525—ab
Uremia with facial paralysis and intestinal ulceration, (25) 1766
Ureter See also Ureters
Ureter, accessory, cystic dilatation of, (168) 1763
and kidney, calculi in, *1001
and kidney pelvis, migration of calculi through walls of, (56) 893
anomalies of, (67) 1226
calculus in, (84) 1765
calculus in pelvic portion of, diagnosis of, (3) 529
calculus, technic of operations for, (1) 2091
catheterization of, for dislodging calculi, (163) 263
catheterization with infected urine, and cystoscopy with turbid urine, (83) 809
catheter, shadowgraph, in diagnosis of obscure lesions of urinary organs, (71) 252
changes in kidneys from experimental ligation of, (160) 255
deformities, classification of, (39) 627
deformity, hydronephrosis from, (83) 2189
divided, anastomotic repair of, (154) 1233—ab, (113) 1844—ab
in fistula, operative treatment of vesicovaginal fistula with participation of, (43) 627
in women, plastic operation to close defects in, (113) 895
left, calculus impacted in, removed through cystoscope, (37) 245
left, perforation of intramural portion of, by calculus, (36) 1689
mouths, graphic registration of renal secretion and its ejaculation from, (47) 90
occlusion of, by non malignant bladder tumor, (71) 443
pelvic, in little girl, multiple calculi in, (45) 90
right kidney and their blood vessels, absence of, (147) 894
right, transplantation of, into appendix (153) 170
strictures of, congenital, (60) 1261
Ureteral fistulas, permanent, and colotomy openings, (5) 1606
Ureterocystostomy, (114) 1683—ab
Ureters See also Ureter
Ureters, catheterization of, (52) 722
catheterization of, importance of occult blood in separate urines obtained by, (126) 1764
catheterization of, and intravesical segregation of urine, (49) 441—ab, (45) 974, (61) 1226, (43) 1688, (66) 1768
implantation of, in rectum, (177) 899
supernumerary, treatment of, (102) 1941
surgery of, (131) 1148
transplanting of, into intestines, ascending infection of kidney carried out by, (50) 966—ab
Urethra and bladder, male, concrements in, (176) 899
anterior, improved operating and observation endoscope for, (17) 2094
deep, and bladder, argyrol injected into, poisoning with, (109) 720
diverticulum of, congenital, (77) 629
douche, massage of, (67) 1768
electrolysis of, technic for, (48) 90
female, primary carcinoma of, (47) 532—ab
fistula of, (25) 896,
infections of, bacterin therapy in, (149) 894
male, accidental cauterization of, with concentrated silver nitrate solution, recovery, (36) 531
male, hemorrhages from, (151) 894
male, stenosis of, congenital, (130) 2191
male, traumatic rupture of fixed portion of, *2048
meatus, technic of section of, (42) 627
Urethra, perineal transplantation of, cancer of penis and extirpation of organ with, (31) 1144
posterior, abscess in, surgery of, resulting fistulae, (32) 531
prolapse of, (27) 622
prostatic, (14) 251
prostatic, inflammatory stricture of, (65) 1768—ab
stone formed in, around piece of wood introduced into urethra 23 years before removal of stone, (39) 537—ab
stricture of, (8) 1410
stricture of and fistulas, treatment of, (15) 2310
stricture of, diagnosis of, (50) 2192
stricture of, electrolysis in, (64) 1768
stricture of incontinence of urine from, (107) 177
stricture of, traumatic, rapid postoperative recurrences of, (44) 625—ab
use of appendix for, and lower cecum as receptacle for urine in exstrophy of bladder, (171) 1064—ab
Urethral and periurethral complications of gonorrhea, their sequelae, (132) 1764
catheter and cystoscope, (31) 1303
Urethritis, chronic, diagnosis and treatment, (41) 2268
chronic, electrode for ionization of silver, zinc, or copper in, *27
chronic, operative treatment of, (39) 1927
chronic, specific, culture of lactic acid in, (7) 1320—ab
gonorrheal chronic, treatment of, (49) 1225
non gonorrheal, (41) 628—ab
non gonorrheal, cell inclusions in, (126) 259
specific, infections in, (111) 1596-ab
Urethrocystitis, influenzal, acute, (150) 1249—ab
Urethroscopy and electrolysis, apparatus for, (45) 90
Urethrotomy, external, without guide, (2) 717—ab
external when should it be done? (47) 2268
Uric acid in gout (125) 1844
physiologic origin of, (116) 970
Uricacidemia, radium emanations in, (144) 2192
Urinary apparatus, tuberculosis of, bacteriologic examination in, (71) 1689
apparatus, tuberculosis of, tuberculin in, (60) 1689
calculi, (31) 531
calculus in Sierra Leone, (25) 254
discomforts of elderly men, relief of, (24) 1144
disease, accuracy in diagnosis of, (3) 529
disturbances after earthquakes in Italy since 1904, (54) 1055
infection, hemophilic bacillus found in, (52) 1054—ab
obstruction due to diseases of verumontanum, (146) 252
organs, disorders of, vicious circles in, (4) 890
organs, value of shadowgraph ureteric catheter in diagnosis of obscure lesions of, (71) 252
passages, B coli infection of, (112) 1237
tract, B coli infection of, complicating pregnancy, (42) 822, (22) 1057
tract, B coli infection of, in children, (9) 1765, (50) 2096—ab
tract, bacterial vaccines in pyogenic infections of, (22) 1320
tract, hematuria in surgical conditions of, (128) 1306
tract of infant, suppuration in, (72) 1418—ab
tract, tuberculosis of, value of tuberculin in, (21) 1320
Urine, acidity of, (114) 1526—ab
albumin content of, rapid determination of, (148) 1232—ab
albuminoids in, in parturient, (60) 529
ammonia in, neutralizing function of, (92) 174
ammonia nitrogen in, improvement of Folin method for determination of, (54) 2013—ab
and blood, lipoid substances in, in tuberculosis, (52) 1417
and feces, estimation of saccharin in, (215) 1225—ab
Urine and sputum, diagnostic importance of microscopic lipoids in, (93) 1320
bacteria in, pathogenic, (24) 348
bile pigments in, in pneumonia, (116) 1320
chlorids in, quantitative determination of, (52) 572—ab
diabetic, ammonia in, Ronchese-Malfatti test for, (103) 725, (147) 813—ab
elimination of radioactive substances in, (123) 603
findings in diagnosis of carcinoma, (74) 1001—ab
from urethral stricture, incontinence of, (107) 177
gas in, (170) 1835
grape-sugar in, colorimetric determination of, (125) 1225
graphic registration of secretion of, and its ejaculation from ureter mouths, (47) 90
healthy, sugar in, as source of osazone reaction, (8) 355
incontinence of, (23) 256
incontinence of, epidural injections in, (51) 90—ab
in diabetes chemical examination of, (175) [illegible]—ab
in pulmonary tuberculosis, chemistry of, (10) 625—ab
indican in, (60) 1522
indican in, tests for, *855
infected, ureter catheterization with, (83) 809
intravesical segregation of, and catheterization of ureters, (49) 441—ab, (45) 974, (61) 1226, (43) 1688, (66) 1768
jet, character of, (47) 90
lower cecum as receptacle for, utilizing appendix for urethra, in exstrophy of bladder, (171) 1064—ab
method of treating and preserving large quantities of, for inorganic analysis, (56) 719
mucous casts in, (109) 175
nitroprussid reaction in, (116) 93
of infants, amino-acids in, (104) 1237
Piroff's levulose reaction in, slight clinical value of, (65) 1417
pepsin in, sign of gastric cancer, (72) 1689
preparation of creatinin from (57) 2013
purin metabolism and elimination in, in chronic rheumatism, (144) 1832
red indican, clinical significance, Metchnikoff theory, (88) 1055—ab
retention of, (36) 1057
retention of, chronic without mechanical obstacle, (60) 1059—ab
saccharin in, determination of, (114) 1524—ab
secretion of, rhythm of, and diuresis induced by ingestion of water, clinical study of, (61) 898—ab
sediments, durable specimens of, (86) 1691
segregated, test of kidney functioning by determination of proportion of diastase eliminated in, (53) 975—ab
serologic behavior of, (145) 447
spontaneous appearance of indigo blue in, (7) 2310—ab
stomach ferments in, diagnostic significance of, determination of, (78) 356
sugar in, modification of Almen's qualitative test for, (72) 2103
sugar in safranin test for, (197) 1596—ab
sulphur in, determination of, (59, 61) 2013—ab
test, urochromogen, and Diazo reaction, (125) 1532—ab
trimethylamin in, alleged occurrence of, (54) 719
tubercle bacilli not found in, in pulmonary tuberculosis, (34) 2273
tuberculous, Diazo reaction in, (108) 260
turbid, cystoscopy with, and ureter catheterization with infected urine, (83) 809
Urines, separate, obtained by ureteral catheterization, occult blood in, (126) 1764
Urologic atrocities, (132) 1764
Urology, bismuth paste in, (28) 627—ab
Urorythmography, (47) 90
Urticaria caused by sun rays, (8) 620
papular forms in children, (35) 349
colon irrigation in, (10) 606—ab

  supplies public, and general and specific mortalities, (151) 534
  supplies public, mortality decrease following purification of, Mills *Reincke phenomenon and Hazen's* theorem on, (48) 1054—ab
  supply and typhoid in Louisville, (132) 1148
  supply and typhoid in Milwaukee, *211
  swimming bath, bacteriologic examination of condition of, (4) 1056
Waters, mineral, action of, on metabolism, (96) 976
  mineral, alkaline saline, action of, on gastric secretion, (57) 1037—ab
  mineral, as artificial serums, (30) 1766
Waters, mineral, cold, ingested fast*ing, evacuation from stomach of,* (47) 628
  mineral, employed internally, mode of action of, (28) 966
  mineral, Kissingen, research on retention of, in stomach, (91) 92
  mineral, of Saratoga Springs as therapeutic agents, (40) 2013
  of Bad Nauheim, therapeutic effect of, (8) 1679
  thermal, Vichy, action of, on arterial tension, (64) 808
Weight, height and epiphyseal development in boys and girls, comparison of, (49) 967—ab
  normal, in proportion to height, (75) 975
  of and nourishment for nursing women, (77) 1418
  of new born infants, nature of physiologic decline in, (108) 1941
  pneumonia and acute fluctuations in, in dyspeptic infants, (120) 1238—ab
  treatment, superheated air and vibratory massage in conservative gynecology, (80) 356
What, not blind yet? (23) 1499
Whey, importance of reduction of, in infant feeding, (92) 444
Whooping cough, (115) 1414
  and its complications, (67) 349
  combined quinin and hydropathic treatment of, (10) 1765—ab
  convulsions in, (89) 2189—ab
  convulsions in, treatment, (103) 358—ab
  encephalitis after, (97) 895—ab
  hot baths in, (143) 1512—ab
  purpura hemorrhagica in, *1201
  suppurative thyroiditis during, (61) 1938
  treatment of, (140) 813—ab
  with gastro intestinal complications, epidemic of, (51) 628—ab
Wire, advantages of, to hold fractured femur, (149) 634
  carrier for bone suture, (97) 2014
  loop for drawing up corner of mouth in cosmetic treatment of facial paralysis, (69) 443—ab
Wiring, ununited fracture of tibia treated by, (21) 255
Wives, future, how should health of, be safeguarded? (73) 624—ab
Woman, functional disorders of bladder in (139) 888
  lying in how long should she stay in bed? (124) 1156—ab
  nursing, influence of diet of, on lactation, (116) 542—ab
  pregnant, acute yellow atrophy of liver following two chloroform anesthesias in quick succession in, 368
  pregnant, successful operation for ileus in, nearly at term, (168) 362
  puerperal, care of, (63) 1762, (50) 1841
  sphere of in medicine, (4) 1686
  varicocele in, (38) 434
Women, appendicitis in, deceptive form of, (91) 802—ab
  biology of blood in, during pregnancy, (87) 2189
  cancer in, and duty of medical profession, (36) 1321—ab
  cancer in statistics of, (75) 1932 ab
  coli cystitis in, etiology, symptomatology and treatment of, (153) 1845
  constipation in, prevention of, (22) 88
  function of corpus luteum, experimental production of maternal placenta and mechanism of sexual cycle in, (17) 166—ab
  gonococcus infections in, (63) 1594, (68) 1682
  medical, needed in India (168) 87
  nervous troubles of, laceration of cervix and perineum a factor in, (116) 1148
  nursing, nourishment for and weight of, (77) 1418
  pelvic organs in influence of trauma in production of diseases of, (81) 801—ab
  plastic operation to close defects in ureter in, (113) 895
  pregnant and puerperal, renal activity in revealed by phenolsulphonephthalein test *20 8
  pregnant, varicocele in, (93) 2159—ab
  procidentia uteri in, intramural sequestration and fixation of uterus for when pregnancy is not pos*sible, (36) 434*

Women, reimplantation of pelvic kidney in, successful, (50) 532
  sterilization of, under certain conditions, (122) 1596
  sterilization of, tubal, (59) 539—ab
  sterilization of, with x rays, (128) 1239—ab
  stricture of lower intestines from inflammation outside in, (65) 1059—ab
  young, menorrhagia in, treatment of, (138) 1934
Wood, splinter of, in left orbit for fifteen years, (96) 720
Work, close, prescribing of lenses for, *110
  epidemiologic, need of quantitative methods in, (152) 534
  manual, in functional nervous diseases *295
Workman's compensation contemporary, for industrial injuries, (131, 135) 534
Workmen's compensation act of 1906, *working of*, (14) 626
  compensation, disputed cases on, (82) 2021
World, trip around, (19) 718
Worms See also Helminths and Helminthiasis
Worms, thread, in appendix, *127
Wound, gunshot, fatal, *1892
  gunshot, of brain, (22) 1144, (8) 1760—ab
  gunshot, of chest and injury to spine, *944
Wound, gunshot, of knee, arthrotomy for, (72) 349
  gunshot of spinal cavity, (42) 172
  healing and mortality rate of 156 consecutive laparotomies, results of, (17) 2311
  infection, analysis of, in 1,000 consecutive clean operative cases, (23) 1680—ab
  infection and puerperal wound intoxication, (80) 1932—ab
  margins, widely separated, approximation of, *2282
  operation, B coli infection of, *1519
  perforating, of uterus, (125) 2270
  postoperative care of, (38) 2013
  stab, of large blood vessel, (56) 1417
Wounded, arrangement for carrying, *in railroad cars*, (128) 812
Wounds, abdominal, useful stitch for *overlapping fascia in closure of*, (79) 253—ab
  drainage and dressing of, in minor surgery, (15) 434
  gunshot, experimental, of skull, (140) 447
  gunshot, of abdomen, (23) 440, (64) 1322
  gunshot, of heart, (112) 1061
  gunshot, of intestine, (163) 889
  gunshot, unusual, (154) 352
  heart, experimental, healing of, (83) 2312
Wounds, healing sluggishly, and leg ulcers, heliotherapy for, (47) 807
  in denervated skin areas, healing of, and its bearing on theory of trophic nerves, (87) 1413—ab
  influence of metabolic disturbances and intoxication on healing of, (60) 1850
  iodin benzin for, (80) 1153
  of eyeball in which foreign body can neither be seen nor accounted for, x ray examination in, (87) 720
  of heart, treatment of, (72) 435—ab
  of intestine, intra intestinal hemorrhage after, (56) 1500
  on body surface, fundamental principles underlying treatment of, *2025
  penetrating, of abdomen illustrating recuperative power in natives of India, (11) 2310
  penetrating, *of chest and abdomen*, (167) 170
  scarlet red *salve for*, (36) 1327
  stab, of diaphragm, operative treat*ment of*, (30) 2312—ab
  stab, sensory tracts in spinal cord after, (171) 302—ab
  stimulating influence of silver nitrate *in form of* powder on healing of, (123) 1331
  suture of, *2282
  thyroid treatment for, (116) 895—ab
  treatment of, (160) 889—ab, (67) 1828, *2149
Wounds, treatment of, surgical dressings and applications, (26) 2004
Wrist dislocation of, forward, spontaneous, (120) 888
  gonorrheal arthritis of, *493
Writing, art of, without use *of eyes*, (141) 1764—ab

Y

Yaws, case of, (84) 1055
  experimental, in monkey and rabbit, (81) 1146
  tertiary, (24) 354
Yeast *fungi in connection with* acetic aldehyd in alcoholic fermentation, (36) 172
Yellow fever, (26) 722
  and health of American citizens, (118) 436
  permanent elimination of, *651
  symptomatology of, (72) 719

Z

Zein and edestin, analysis of, (129) 534
Zinc, electrode for ionization of, in *chronic urethritis*, *27
  sulphate, poisoning by, (38) 256
Zoology problems and achievements of recent research in, (86) 1607

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

In this Index are the names of the authors of articles which have appeared in The Journal of the American Medical Association and of articles which have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. Thus it practically includes the names of all who have published articles in the leading journals of the world during the past six months To add to its completeness, the names have been added of those who read papers before societies as published in The Journal. The * preceding the page reference indicates that the article appeared in full in The Journal. The numbers in parentheses indicate the numbered paragraphs on the pages referred to. The numbers not in parentheses indicate pages.
